#### ACKNOWLEDGEMENTS

First and foremost, I would like to thank my wife and children, to whom this work is dedicated. I owe a special debt to my wife Claire for enduring a struggle greater than either of us imagined at the outset. Her ability to find kind words at the most difficult times meant more that mere words can convey.

I would like to extend my deep thanks and gratitude to my advisor Philip Gill. His support, patience, insight and enthusiasm have fueled this process from beginning to end. Philip provided me with both financial assistance and friendly support. In addition, he showed great patience and understanding in dealing with an older graduate student with dependents. His contributions to one of the most significant chapters of my life will never be forgotten.

For their part in this chapter, I would like to thank the other members of my committee as well. I thank Ben Rosen for his friendship and research motivation. I came to admire Ben while working with him as a Research Assistant. I would also like to personally thank Jim Bunch for his friendship and occasional advice, both were welcome. For their time and effort on my behalf, I thank Randy Bank and Richard Belew.

I owe a special thanks to Michael Saunders of the Stanford Optimization Laboratory. I am grateful for his priceless insights on LSQR, MINOS and SNOPT, and for his helpful suggestions on the third chapter. I will forever be in awe of Michael's and Philip's numerical software skills.

I thank the National Science Foundation for providing the majority of my financial support during my time at UCSD.

I would like to thank Lois Stewart and Natalie Powell for helping to keep me afloat in times of trouble.

Finally, I would like to give thanks to my friends and extended family. There are far to many to mention, but their sincere acts of kindness and support, both large and small, are neither forgotten nor taken for granted.

#### ABSTRACT OF THE DISSERTATION

#### SQP Methods for Large-Scale Optimization

by

Alexander Barclay

Doctor of Philosophy in Mathematics

University of California San Diego, 1999

Professor Philip Cill, Chair

Professor Philip Gill, Chair

Sequential quadratic programming methods have proved highly effective for solving constrained optimization problems with smooth nonlinear functions in the objective and constraints. Sequential quadratic programming methods solve a sequence of quadratic programming (QP) subproblems, where each iteration of the QP subproblem requires the solution of a large linear system for the search direction. For some problems, the number of degrees of freedom,  $n_z$ , is of moderate size (say, up to 1000), and the large system can be solved using two smaller dense systems, one for the QP search direction and one for the QP multipliers. In this case, the system for the search direction is  $Z^THZp = -Z^Tg$ , where  $Z^THZ$  is an  $n_z \times n_z$  reduced Hessian.

The thesis is concerned with the formulation and analysis of two sequential quadratic programming algorithms that are designed to be efficient when  $n_z$  is large  $(n_z \gg 1000)$ . The first method uses the conjugate-gradient method to solve the linear systems. The reduced system is shown to be equivalent to a certain least-squares problem that can be solved using the conjugate-gradient algorithm LSQR. Two preconditioners are proposed to accelerate convergence. The conjugate-gradient algorithm is implemented in a large-scale sequential quadratic programming method based on the optimization code SNOPT. Numerical results

are presented to demonstrate the efficiency of the algorithm for problems with large degrees of freedom.

The second method uses a Schur-complement approach to solve a large sparse system derived directly from the optimality conditions. The search directions are calculated using a fixed large sparse system and a small dense system incorporating the changes to the active set at each QP iteration. A general algorithm for convex quadratic programming is discussed, and a Schur-complement method is formulated for use with the algorithm. In addition, a new Schur-complement method is derived for minimizing an  $\ell_2$  composite objective function when the initial point is not feasible. Modifications to the standard QP algorithm are presented that allow the use of a composite objective.

# Chapter 1

# Introduction

Large-scale sequential quadratic programming (SQP) methods have proved highly effective for solving constrained optimization problems of the form

where l and u are constant upper and lower bounds, f(x) is a smooth nonlinear function, G is a sparse matrix, F(x) is a vector of smooth nonlinear constraint functions  $\{F_i(x)\}$ , and n is large  $(n \gg 1000)$ . The upper and lower bounds l and u allow for the general description of various types of bounds and constraints. For instance, free rows and unbounded variables are represented by setting the appropriate  $l_i = -\infty$  and  $u_i = +\infty$ . Equality constraints and fixed variables are represented by setting  $l_i = u_i$ . If F(x) is not present, and if f(x) is linear, then problem NP defines a linear program.

The success of SQP methods on practical problems of this form has inevitably lead to a substantial increase in expectation. As SQP methods have gained acceptance as a numerical tool, the size and difficulty of the problems attempted has inevitably increased. It is crucial that new SQP methods be developed for problems that cannot yet be solved efficiently by using existing technology.

## 1.1 Description of a SQP Method

A particular large-scale SQP method is implemented in the optimization code SNOPT [16]. The SQP method used in SNOPT first converts problem NP to an equality constrained problem with simple bounds. The upper and lower bounds on the m components of F and Gx are said to define the general constraints of the problem. SNOPT converts the general constraints to equalities by introducing a set of slack variables s, where  $s = (s_1, s_2, \ldots, s_m)^T$ . For example, the linear constraint  $5 \le 2x_1 + 3x_2 \le +\infty$  is replaced by  $2x_1 + 3x_2 - s_1 = 0$  together with the bounded slack  $5 \le s_1 \le +\infty$ . The problem NP can therefore be rewritten in the following equivalent form

minimize 
$$f(x)$$
  
subject to  $\begin{pmatrix} F(x) \\ Gx \end{pmatrix} - s = 0, \quad l \le \begin{pmatrix} x \\ s \end{pmatrix} \le u.$  (1.1)

The linear and nonlinear general constraints become equalities of the form  $F(x) - s_N = 0$  and  $Gx - s_L = 0$ , where  $s_L$  and  $s_N$  are known as the linear and nonlinear slacks.

The basic structure of a SQP method involves major and minor iterations. The major iterations generate a sequence of iterates  $(x_k)$  that satisfy the linear constraints. The iterates  $(x_k)$  converge to a point that satisfies the first-order conditions for optimality. At each iterate, a quadratic programming (QP) subproblem is used to generate a search direction towards the next iterate  $(x_{k+1})$ . Solving the QP subproblem is itself an iterative procedure, with the minor iterations of an SQP method being the iterations of the QP method.

## 1.1.1 Major Iterations

In SNOPT, the constraints of the subproblem are formed from the linear constraints  $Gx-s_{\scriptscriptstyle L}=0$  and the nonlinear constraint linearization

$$F(x_k) + F'(x_k)(x - x_k) - s_N = 0,$$

where  $F'(x_k)$  denotes the Jacobian matrix, whose rows are the first derivatives of F(x) evaluated at  $x_k$ . The QP constraints therefore comprise the m linear constraints

$$F'(x_k)x - s_N = -F(x_k) + F'(x_k)x_k,$$

$$Gx - s_L = 0,$$

where x and s are bounded above and below by u and l as before. If the  $m \times n$  matrix A and m-vector b are defined as

$$A = \begin{pmatrix} F'(x_k) \\ G \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} -F(x_k) + F'(x_k)x_k \\ 0 \end{pmatrix},$$

then the QP subproblem can be written as

minimize 
$$\psi(x)$$
 subject to  $Ax - s = b$ ,  $l \le \begin{pmatrix} x \\ s \end{pmatrix} \le u$ , (1.2)

where  $\psi(x)$  is a quadratic approximation to a modified Lagrangian function (see Section 2.1).

#### 1.1.2 Minor Iterations

The QP method of SNOPT is an inertia-controlling active-set method [13, 21]. At each minor iteration of an active-set method, the constraints Ax - s = b are (conceptually) partitioned into the form

$$Bx_B + Sx_S + Nx_N = b,$$

where the basis matrix B is square and nonsingular. The elements of  $x_B$ ,  $x_S$  and  $x_N$  are called the basic, superbasic and nonbasic variables respectively; they are a permutation of the elements of x and s. At a QP solution, the basic and superbasic variables will lie somewhere between their bounds, while the nonbasic variables will be equal to one of their upper or lower bounds. At each iteration,  $x_S$  is regarded as a set of independent variables that are free to move in any desired

direction, namely one that will improve the value of the QP objective (or the sum of infeasibilities). The basic variables are then adjusted in order to ensure that (x,s) continues to satisfy Ax - s = b. The number of superbasic variables  $(n_s)$  say) therefore indicates the number of degrees of freedom remaining after the constraints have been satisfied (or  $n_z \equiv n_s$ ). In broad terms,  $n_s$  is a measure of how nonlinear the problem is. In particular,  $n_s$  will always be zero for LP problems.

If it appears that no improvement can be made with the current definition of B, S and N, a nonbasic variable is selected to be added to S, and the process is repeated with the value of  $n_S$  increased by one. At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of  $n_S$  is decreased by one.

Associated with each of the m equality constraints Ax - s = b are the dual variables  $\pi$ . The dual variables are also known as the Lagrange multipliers. Similarly, each variable in (x,s) has an associated reduced gradient  $d_j$ . The reduced gradients for the variables x are the quantities  $g - A^T \pi$ , where g is the gradient of the QP objective, and the reduced gradients for the slacks are the dual variables  $\pi$ . The QP subproblem is optimal if  $d_j \geq 0$  for all nonbasic variables at their lower bounds,  $d_j \leq 0$  for all nonbasic variables at their upper bounds, and  $d_j = 0$  for other variables, including superbasics.

A more detailed description of the QP method used in SNOPT is given in Chapter 2.

#### 1.1.3 The Merit Function

After a QP subproblem has been solved, new estimates of the NP solution are computed using a line search on the augmented Lagrangian merit function

$$\mathcal{M}(x, s, \pi) = f(x) - \pi^{T}(F(x) - s_{N}) + \frac{1}{2}(F(x) - s_{N})^{T}D(F(x) - s_{N}), \tag{1.3}$$

where D is a diagonal matrix of penalty parameters. If  $(x_k, s_k, \pi_k)$  denotes the current solution estimate and  $(\hat{x}_k, \hat{s}_k, \hat{\pi}_k)$  denotes the optimal QP solution, the

line search determines a step  $\alpha_k$  (0 <  $\alpha_k \le 1$ ) such that the new point

$$\begin{pmatrix} x_{k+1} \\ s_{k+1} \\ \pi_{k+1} \end{pmatrix} = \begin{pmatrix} x_k \\ s_k \\ \pi_k \end{pmatrix} + \alpha_k \begin{pmatrix} \hat{x}_k - x_k \\ \hat{s}_k - s_k \\ \hat{\pi}_k - \pi_k \end{pmatrix}$$

gives a sufficient decrease in the merit function (1.3). When necessary, the penalties in D are increased by the minimum-norm perturbation that ensures descent for  $\mathcal{M}$  [22]. In SNOPT,  $s_N$  is adjusted to minimize the merit function as a function of s prior to the solution of the QP subproblem. For more details, see [18, 9].

#### 1.1.4 Treatment of Constraint Infeasibilities

SNOPT makes explicit allowance for infeasible constraints. Infeasible linear constraints are detected first by solving a problem of the form

where e is a vector of ones. This is equivalent to minimizing the sum of the general linear constraint violations subject to the simple bounds. (In the linear programming literature, the approach is often called *elastic programming*.)

If the linear constraints are infeasible  $(v \neq 0 \text{ or } w \neq 0)$ , SNOPT terminates without computing the nonlinear functions.

If the linear constraints are feasible, all subsequent iterates satisfy the linear constraints. (Such a strategy allows linear constraints to be used to define a region in which the functions can be safely evaluated.) SNOPT proceeds to solve NP as given, using search directions obtained from a sequence of quadratic programming subproblems (1.2).

If a QP subproblem proves to be infeasible or unbounded (or if the dual variables  $\pi$  for the linearized constraints become large), SNOPT enters "elastic" mode

and solves the problem

where  $\gamma$  is a nonnegative parameter (the *elastic weight*), and  $f(x) + \gamma e^{T}(v + w)$  is called a *composite objective*. If  $\gamma$  is sufficiently large, this is equivalent to minimizing the sum of the nonlinear constraint violations subject to the linear constraints and bounds. A similar  $\ell_1$  formulation of NP is fundamental to the  $S\ell_1QP$  algorithm of Fletcher [11]. See also Conn [8].

## 1.2 Contributions of this Thesis

The general focus of the thesis research is on using iterative methods to solve the QP subproblems within an SQP method. Currently, SNOPT solves the QP subproblems by solving a series of linear systems of the form

$$Z^T H Z p_z = -Z^T g, (1.4)$$

where  $Z^T H Z \in \mathbb{R}^{n_S \times n_S}$ , with  $n_S < n$ . SNOPT is well suited for problems where the number of degrees of freedom,  $n_S$ , is of moderate size (say, up to 1000).

The primary objective of this dissertation is to develop QP algorithms that are efficient when  $n_s$  is large ( $n_s \gg 1000$ ), for use within an SQP algorithm such as SNOPT. Two different large-scale QP algorithms are investigated.

- 1. A conjugate-gradient (CG) method is used to solve the linear system,  $Z^T H Z p_Z = -Z^T g$ . This method includes the definition of two different preconditioners for accelerating convergence.
- 2. A Schur-complement (SC) algorithm is investigated for solving the

Karush-Kuhn-Tucker (KKT) systems associated with (1.2),

$$\begin{pmatrix} H & W^T \\ W & 0 \end{pmatrix} \begin{pmatrix} u \\ \lambda \end{pmatrix} = \begin{pmatrix} g \\ 0 \end{pmatrix}.$$

See Section 4.1.

#### The Conjugate-Gradient Method

The CG method solves the reduced-Hessian systems (1.4) by solving an associated least-squares problem. This allows the use of a least-squares CG algorithm. This approach benefits from the numerical advantages of using a least-squares CG algorithm instead of a general symmetric CG algorithm for solving linear systems. Critical to the successful implementation of the CG method is the calculation and maintenance of appropriate preconditioners for the associated least-squares problem. The thesis investigates the use of block diagonal preconditioners, with a dense upper-triangular block, and a larger diagonal extension.

The numerical results demonstrate the potential of the CG method on problems with as many as 5625 degrees of freedom. The performance is particularly good on unconstrained and nonlinearly constrained problems. The need for preconditioning is evident on some problems. However, when the number of CG iterations is small relative to the size of the linear system, the benefits of the preconditioner are overwhelmed by its cost.

The workspace size on the computer used for the test results limited the size of the problems attempted. In the future it should be possible to run problems with tens of thousands of degrees of freedom. It is assumed that this will show an even greater benefit from the CG method, and the preconditioners.

The use of a CG method to solve the QP subproblems within an SQP method has not been investigated elsewhere. However, a similar approach is used by Chen et al. [7] for linear programming, where the linear systems of a primal-dual log barrier algorithm are solved as a least-squares problem using a least-squares CG algorithm. One of the preconditioners investigated in the thesis uses a block diagonal quasi-Newton approximation. In related work, Morales and Nocedal [29]

discuss using a CG algorithm with a limited-memory quasi-Newton preconditioner for solving a sequence of linear systems where the coefficient matrix and right-hand side are changing. However, their work is directed towards Hessian-free Newton methods and finite-element problems.

#### The Schur-Complement Method

A SC method is investigated for solving the QP subproblems. The method extends the work of Gill et al. [20, 21]. The general SC concept of using a fixed factorization of an initial KKT system, and an updated factorization of a smaller, dense Schur complement, is preserved. However, the thesis extends this to define the algorithm in terms of an extended KKT system, whose working set may consist of constraints whose residual is not necessarily zero. This allows a new Schurcomplement QP method to be defined that only requires a positive-semidefinite Hessian. In addition, by proper formulation of the algorithm, some of the solves with the initial KKT system are avoided.

Particular attention is given to addressing an infeasible initial point. A new SC algorithm is derived using an  $\ell_2$  quadratic penalty function for the QP objective. The use of a composite objective function reduces the number of working set changes to the dense Schur complement when finding a feasible point. The choice of the  $\ell_2$  norm places fewer restrictions on the working set, by not requiring it to be linearly independent at each step. A linearly independent working set is only required when the penalty parameter becomes large.

The thesis is organized as follows. Chapter 2 presents background on the SQP method of SNOPT, with particular attention on the QP algorithm used in SNOPT. The conjugate-gradient QP method is presented in Chapter 3, including some numerical results on a subset large problems from the CUTE test suite [4]. The Schur-complement QP method is presented in Chapter 4.

## 1.3 Notation

Unless otherwise indicated, the following notation is used throughout the dissertation.

Capital letters are used to represent matrices, lowercase letters represent vectors and Greek letters represent scalars.

For a matrix, the corresponding lowercase letter with a subscript represents a column of the matrix. For instance,  $h_i$  will be the *i*-th column of the matrix H. An element of a matrix is indicated by a double indexed subscript of the associated lowercase letter, i.e.,  $h_{ij}$  will be the ij-th element of H.

Bracketed vectors with a subscript indicate an element of a vector. For example,  $(v)_i$  would be the *i*-th element of the vector v.

The vector  $e_t$  is the t-th column of the identity. The lowercase e is reserved for a vector of all ones. In all cases, the dimension will depend on the context.

The norm  $\|.\|$  is assumed to be the two-norm.

# Chapter 2

# Background

The QP solver used in SNOPT (that of SQOPT [15]) is based on an inertiacontrolling method that maintains a Cholesky factorization of the reduced Hessian (see Section 2.2). The method follows Gill and Murray [13] and is described in [21]. This chapter briefly summarizes the main features of the method.

SQOPT solves the QP subproblem given in Chapter 1 as

minimize 
$$\psi(x)$$
 subject to  $Ax - s = b$ ,  $l \le \begin{pmatrix} x \\ s \end{pmatrix} \le u$ . (2.1)

Since the slack variables are subject to the same upper and lower bounds as the components of Ax, they allow us to think of the bounds on Ax and x as simply bounds on the combined vector (x, s). (In order to indicate their special role in problem (2.1), the original variables x are sometimes known as "column variables", and the slack variables s are known as "row variables").

SQOPT's method has a feasibility phase (also known as phase 1), in which a feasible point is found by minimizing the sum of infeasibilities, and an optimality phase (or phase 2) in which the quadratic objective is minimized within the feasible region. The computations of both phases are performed by the same subroutines, with the change of phase being characterized by the objective changing from the sum of infeasibilities to the quadratic objective.

In general, an iterative process is required to solve a quadratic program. Given an iterate (x, s) in both the original variables x and the slack variables s, a new iterate  $(\bar{x}, \bar{s})$  is defined by

$$\begin{pmatrix} \bar{x} \\ \bar{s} \end{pmatrix} = \begin{pmatrix} x \\ s \end{pmatrix} + \alpha p, \tag{2.2}$$

where the step length  $\alpha$  is a non-negative scalar, and p is called the search direction. (For simplicity, the reference to the index of the iteration is dropped.) Once an iterate is feasible (i.e., satisfies the constraints), all subsequent iterates remain feasible.

## 2.1 Definition of the Objective Function

For this section, let  $x_k$  and  $\pi_k$  be estimates of the solution and the Lagrange multipliers of problem NP at the k-th major iteration. The SQP algorithm implemented in SNOPT is based on the *modified Lagrangian* associated with problem NP, namely

$$\mathcal{L}(x, x_k, \pi_k) = f(x) - \pi_k^T d_L(x, x_k), \tag{2.3}$$

which is defined in terms of the *constraint linearization* and the *departure from linearity*:

$$c_L(x, x_k) = c(x_k) + J(x_k)(x - x_k),$$
  
 $d_L(x, x_k) = c(x) - c_L(x, x_k);$ 

see Robinson [33] and Van der Hoek [34]. The first and second derivatives of the modified Lagrangian with respect to x are

$$\nabla \mathcal{L}(x, x_k, \pi_k) = g(x) - (J(x) - J(x_k))^T \pi_k,$$
$$\nabla^2 \mathcal{L}(x, x_k, \pi_k) = \nabla^2 f(x) - \sum_i (\pi_k)_i \nabla^2 c_i(x).$$

Observe that  $\nabla^2 \mathcal{L}$  is independent of  $x_k$  (and is the same as the Hessian of the conventional Lagrangian). At  $x = x_k$ , the modified Lagrangian has the same function and gradient values as the objective f(x):

$$\mathcal{L}(x_k, x_k, \pi_k) = f(x_k), \qquad \nabla \mathcal{L}(x_k, x_k, \pi_k) = g(x_k).$$

The objective of the QP subproblem is a quadratic model of  $\mathcal{L}$  (2.3), which (ignoring constant terms) is given by

$$\psi(x) = g^T x + \frac{1}{2} x^T H x,$$

where g is the gradient of f(x) at the current  $x_k$ , and H is a positive-definite approximation to Hessian of the modified Lagrangian function.

#### 2.1.1 The Approximate Hessian

On completion of the line search, let the change in x and the gradient of the modified Lagrangian be

$$\delta_k = x_{k+1} - x_k \quad \text{and} \quad y_k = \nabla \mathcal{L}(x_{k+1}, x_k, \pi) - \nabla \mathcal{L}(x_k, x_k, \pi), \tag{2.4}$$

for some vector  $\pi$ . An estimate of the curvature of the modified Lagrangian along  $\delta_k$  is incorporated using the BFGS quasi-Newton update,

$$H_{k+1} = H_k + \theta_k y_k y_k^T - \phi_k q_k q_k^T, \tag{2.5}$$

where  $q_k = H_k \delta_k$ ,  $\theta_k = 1/y_k^T \delta_k$  and  $\phi_k = 1/q_k^T \delta_k$ . When  $H_k$  is positive definite,  $H_{k+1}$  is positive definite if and only if the approximate curvature  $y_k^T \delta_k$  is positive. Precautions are taken against a negative or small value of  $y_k^T \delta_k$  [16].

The updated multipliers  $\pi_{k+1}$  from the line search are chosen for  $\pi$ , and the definition of  $\mathcal{L}$  (2.3) yields

$$y_k = \nabla \mathcal{L}(x_{k+1}, x_k, \pi_{k+1}) - \nabla \mathcal{L}(x_k, x_k, \pi_{k+1})$$
  
=  $g(x_{k+1}) - (J(x_{k+1}) - J(x_k))^T \pi_{k+1} - g(x_k).$ 

In the large-scale case,  $H_k$  cannot be treated as an  $n \times n$  dense matrix. Section 2.1.3 discusses the limited-memory quasi-Newton scheme implemented in SNOPT.

#### 2.1.2 Linear Variables

If only some of the variables occur nonlinearly in the objective and constraint functions, they are referred to as linear variables. If there are linear variables, the Hessian of the Lagrangian has structure that can be exploited during the optimization. Assume that the nonlinear variables are the first  $\bar{n}$  components of x. By induction, if  $H_0$  is zero in its last  $n - \bar{n}$  rows and columns, the last  $n - \bar{n}$  components of the BFGS update vectors  $y_k$  and  $H_k\delta_k$  are zero for all k, and every  $H_k$  has the form

$$H_k = \begin{pmatrix} \bar{H}_k & 0\\ 0 & 0 \end{pmatrix}, \tag{2.6}$$

where  $\bar{H}_k$  is  $\bar{n} \times \bar{n}$ . A QP subproblem with Hessian of this form is either unbounded, or has at least  $n - \bar{n}$  constraints in the final working set. This implies that the reduced Hessian need never have dimension greater than  $\bar{n}$ .

In order to treat semidefinite Hessians such as (2.6), SQOPT includes an *inertia* controlling working-set strategy, which ensures that the reduced Hessian has at most one zero eigenvalue [16].

## 2.1.3 Limited-memory Hessians

To treat problems where the number of nonlinear variables  $\bar{n}$  is very large, a limited-memory procedure is used to update an initial Hessian approximation  $H_r$  a limited number of times. The present implementation is quite simple and has benefits in the SQP context when the constraints are linear.

Initially, suppose  $\bar{n}=n$ . Let  $\ell$  be preassigned (say  $\ell=20$ ), and let r and k denote two major iterations such that  $r \leq k \leq r + \ell$ . Up to  $\ell$  updates to a positive-definite  $H_r$  are accumulated to represent the Hessian as

$$H_k = H_r + \sum_{j=r}^{k-1} \theta_j y_j y_j^T - \phi_j q_j q_j^T,$$
 (2.7)

where  $q_j = H_j \delta_j$ ,  $\theta_j = 1/y_j^T \delta_j$  and  $\phi_j = 1/q_j^T \delta_j$ . The quantities  $(y_j, q_j, \theta_j, \phi_j)$ 

are stored for each j. During major iteration k, the QP solver accesses  $H_k$  by requesting products of the form  $H_kv$ . These are computed by

$$H_k v = H_r v + \sum_{j=r}^{k-1} \theta_j(y_j^T v) y_j - \phi_j(q_j^T v) q_j.$$
 (2.8)

The work for forming vector products with H is 3n(k-r)-2n flops, and n+2 additional multiplications. On completion of iteration  $k=r+\ell$ , the diagonals of  $H_k$  are computed from (2.7) and saved to form the next positive-definite  $H_r$  (with r=k+1). Storage is then "reset" by discarding the previous updates. (Similar schemes are suggested by Buckley and LeNir [5, 6] and Gilbert and Lemaréchal [12].)

If  $\bar{n} < n$ ,  $H_k$  has the form (2.6) and the same procedure is applied to  $H_k$ . Note that the vectors  $y_j$  and  $q_j$  have length  $\bar{n}$ —a benefit when  $\bar{n} \ll n$ .

## 2.2 Definition of the Working Set

At each minor iterate (x, s), a working set of constraints is defined to be a linearly independent subset of the constraints that are satisfied "exactly" (to within the value of a feasibility tolerance). For problem (2.1), the working set consists of the equality constraints Ax - s = b, and the bound constraints for those elements of (x, s) that are on one of their bounds. The working set is the current prediction of the constraints that hold with equality at a solution of the QP. Let  $m_w$  denote the number of constraints in the working set (including bounds), and let W denote the associated  $m_w \times (n+m)$  working-set matrix consisting of the  $m_w$  gradients of the working-set constraints.

The search direction is defined so that constraints in the working set remain unaltered for any value of the step length. It follows that p must satisfy the identity Wp = 0. This characterization allows p to be computed using any  $n \times n_Z$  full-rank matrix Z that spans the null space of W. (Thus,  $n_Z = n - m_w$  and WZ = 0.) The null-space matrix Z is defined from a sparse LU factorization of part of W;

see (2.9)–(2.10) below. The direction p will satisfy Wp = 0 if  $p = Zp_z$  for any  $n_z$ -vector  $p_z$ .

The working set contains the constraints Ax - s = 0 and a subset of the upper and lower bounds on the variables (x, s). Since the gradient of a bound constraint  $x_j \geq l_j$  or  $x_j \leq u_j$  is a vector of all zeros except for  $\pm 1$  in position j, it follows that the working-set matrix contains the rows of (A - I) and the unit rows associated with the upper and lower bounds in the working set.

The working-set matrix W can be represented in terms of a certain column partition of the matrix ( A - I ). We partition the constraints Ax - s = 0 so that

$$Bx_B + Sx_S + Nx_N = 0,$$

where B is a square non-singular basis and  $x_B$ ,  $x_S$  and  $x_N$  are the basic, superbasic and nonbasic variables respectively. The nonbasic variables are equal to their upper or lower bounds at (x, s), and the superbasic variables are independent variables that are chosen to improve the value of the current objective. The number of superbasic variables is  $n_s$ . Given values of  $x_N$  and  $x_S$ , the basic variables  $x_B$  are adjusted so that (x, s) satisfies  $Bx_B + Sx_S + Nx_N = 0$ .

If P is a permutation such that (A - I)P = (B S N), then the working-set matrix W satisfies

$$WP = \begin{pmatrix} B & S & N \\ 0 & 0 & I_N \end{pmatrix}, \tag{2.9}$$

where  $I_N$  is the identity matrix with the same number of columns as N.

The null-space matrix Z is defined from a sparse LU factorization of part of W. In particular, Z is maintained in "reduced-gradient" form, so that

$$Z = P \begin{pmatrix} -B^{-1}S \\ I \\ 0 \end{pmatrix}, \tag{2.10}$$

where P is a permutation. This choice of Z implies that  $n_Z$ , the number of degrees of freedom at (x, s), is the same as  $n_s$ , the number of superbasic variables.

The package LUSOL [19] is used to maintain sparse LU factors of the basis matrix B, which alters as the working set W changes. The matrix Z is used only as an operator, i.e., it is never computed explicitly. Products of the form Zv and  $Z^Tg$  are obtained by solving with B or  $B^T$ . Specifically, the calculation of u = Zv is performed by first computing w = Sv, and then solving By = w using the LU factors of B. The desired vector u is given by

$$u = \begin{pmatrix} y \\ v \\ 0 \end{pmatrix}.$$

If B and S were dense, the work of computing matrix-vector products with Z would be  $m^2 + mn_s$  flops. When the sparse LU factors of B are used, one factor of m is reduced. Forming matrix-vector products with  $Z^T$  is a similar computation. The number of flops required is the same, but an additional  $n_s$  additions are needed to sum terms.

Let  $g_z$  and  $H_z$  denote the reduced gradient and reduced Hessian:

$$g_z = Z^T g$$
 and  $H_z = Z^T H Z$ , (2.11)

where g is the objective gradient at (x,s). Roughly speaking,  $g_z$  and  $H_z$  describe the first and second derivatives of an  $n_z$ -dimensional unconstrained problem for the calculation of  $p_z$ .

At each iteration, an upper-triangular factor R is available such that  $H_Z = R^T R$ . Normally, R is computed from  $R^T R = Z^T H Z$  at the start of phase 2 and is then updated as the QP working set changes. For efficiency, the dimension of R should not be excessive (say,  $n_Z \leq 1000$ ). This is guaranteed if the number of nonlinear variables is "moderate".

If all the constraints are linear, then the computation of R at the start of phase 2 can be avoided. For linear constraints, Z will not change between subproblems. In

addition, since H is a limited-memory quasi-Newton approximation to Lagrangian Hessian, R can be modified for the updates to H at each major iteration. Therefore, the R at the start of each subproblem will be the correct R such that  $R^TR = Z^THZ$ , and the factorization of the reduced-Hessian is not necessary. This implies that SNOPT will be more efficient on problems where all the constraints are linear.

If the QP contains linear variables, H is positive semi-definite and R may be singular with at least one zero diagonal. In this case, an inertia-controlling active-set strategy is used to ensure that only the last diagonal of R can be zero. (See [21] for discussion of a similar strategy for indefinite quadratic programming.)

At the initial point, some variables are fixed at their current value so that enough temporary bound constraints are included in the working set to make R nonsingular. Thereafter, R can become singular only when a constraint is deleted from the working set (in which case no further constraints are deleted until R becomes nonsingular).

## 2.3 The Algorithm SQOPT

## 2.3.1 Computation of the Lagrange Multipliers

If the reduced gradient is zero, (x,s) is a subspace stationary point with respect to the current working set. During phase 1, the reduced gradient will usually be zero only at a vertex (although it may be zero elsewhere in the presence of constraint dependencies). During phase 2, a zero reduced gradient implies that x minimizes the quadratic objective when the constraints in the working set are treated as equalities. At a subspace stationary point, Lagrange multipliers  $\lambda$  are defined from the equations  $W^T\lambda = g(x)$ . A Lagrange multiplier  $\lambda_j$  corresponding to an inequality constraint in the working set is said to be optimal if  $\lambda_j \leq \sigma$  when the associated constraint is at its upper bound, or if  $\lambda_j \geq -\sigma$  when the associated constraint is at its lower bound, where  $\sigma$  depends on the optimality tolerance. If a multiplier is non-optimal, the objective function (either the true objective or

the sum of infeasibilities) can be reduced by continuing the minimization with the corresponding constraint excluded from the working set (this step is sometimes referred to as "deleting" a constraint from the working set). If optimal multipliers occur during the feasibility phase but the sum of infeasibilities is not zero, there is no feasible point.

The special form (2.9) of the working set allows the multiplier vector, the solution of  $W^T \lambda = g$ , to be written in terms of the vector

$$d = \begin{pmatrix} g \\ 0 \end{pmatrix} - (A - I)^T \pi = \begin{pmatrix} g - A^T \pi \\ \pi \end{pmatrix}, \tag{2.12}$$

where  $\pi$  satisfies the equations  $B^T\pi=g_B$ , and  $g_B$  denotes the basic components of g. The components of  $\pi$  are the Lagrange multipliers  $\lambda_j$  associated with the equality constraints Ax - s = b. The vector  $d_N$  of nonbasic components of d consists of the Lagrange multipliers  $\lambda_j$  associated with the upper and lower bound constraints in the working set. The vector  $d_S$  of superbasic components of d is the reduced gradient  $g_Z$  (2.11). The vector  $d_B$  of basic components of d is zero, by construction.

## 2.3.2 Computing the Search Direction

If the reduced gradient is not zero, Lagrange multipliers need not be computed and the search direction is given by  $p = Zp_z$ , where  $p_z$  is defined below. The step length is chosen to maintain feasibility with respect to the satisfied constraints.

There are two possible choices for  $p_z$ , depending on whether or not  $H_z$  is singular. If  $H_z$  is nonsingular, R is nonsingular and  $p_z$  is computed from the equations,

$$R^T R p_Z = -g_Z, (2.13)$$

where  $g_z$  is the reduced gradient at x. In this case, (x,s) + p is the minimizer of the objective function subject to the working-set constraints being treated as equalities. If (x,s) + p is feasible,  $\alpha$  is defined to be one. In this case, the reduced

gradient at  $(\bar{x}, \bar{s})$  will be zero, and Lagrange multipliers are computed at the next iteration. Otherwise,  $\alpha$  is set to  $\alpha_N$ , the step to the boundary of the "nearest" constraint along p. This constraint is added to the working set at the next iteration.

If  $H_Z$  is singular, then R must also be singular, and an inertia-controlling strategy is used to ensure that only the last diagonal element of R is zero. In this case,  $p_Z$  satisfies

$$p_z^T H_z p_z = 0 \quad \text{and} \quad g_z^T p_z \le 0,$$
 (2.14)

which allows the objective function to be reduced by any step of the form  $(x, s) + \alpha p$ ,  $\alpha > 0$ . The vector  $p = Zp_Z$  is a direction of unbounded descent for the QP in the sense that the QP objective is linear and decreases without bound along p. If no finite step of the form  $(x, s) + \alpha p$  ( $\alpha > 0$ ) reaches a constraint not in the working set, the QP is unbounded and SQOPT terminates at (x, s). Otherwise,  $\alpha$  is defined as the maximum feasible step along p and a constraint active at  $(x, s) + \alpha p$  is added to the working set for the next iteration.

As constraints are added to the working set, the working-set matrix W remains full rank.

## 2.3.3 The Active Set Strategy

When the working set changes, it is necessary to update the upper-triangular factor of  $Z^THZ$ . There are two possible changes to the working set, a constraint is either added to, or deleted from, the working set. For problem (2.1), the working set always includes the linear equality constraints, therefore, changes in the working set only involve bound constraints. For this reason, it is common to think of variables being added to, or deleted from, the working set, since each bound constraint is associated with a single variable.

In an active-set method, these changes are defined in terms of the type of variable being added or deleted. When a variable, or constraint, is deleted from the working set, this is equivalent to adding a superbasic variable to the active set. If a constraint is added to the the working set, then either a superbasic or a basic variable is deleted from the active set. Thus, adding or deleting a constraint from the working set corresponds to the removal or addition of a column of S, and possibly the replacement of a column of the basis B. This changes the null-space matrix Z defined by (2.10) and results in a change to  $Z^THZ$ . There are three cases for updating R.

- 1. If a nonbasic variable moves off its bound, the associated column is moved from N to S. This is referred to as adding a superbasic variable.
- 2. If a superbasic variable moves to one of its bounds, the associated column is moved from S to N. This is referred to as deleting a superbasic variable.
- 3. If a basic variable moves to one of its bounds, the associated column is moved from B to N, and an appropriate column of S is moved to B. This is referred to as deleting a basic variable.

Adding a superbasic variable is equivalent to expanding R by a new row and column. The update to Z is given by  $\bar{Z} = (Z - z)$ , where

$$z = \begin{pmatrix} -B^{-1}s_t \\ e_t \\ 0 \end{pmatrix}, \tag{2.15}$$

with  $s_t$  the new column of S. If the update to R is defined as

$$\bar{R} = \left( \begin{array}{cc} R & v \\ 0 & \rho \end{array} \right),$$

then the identity  $\bar{R}^T \bar{R} = \bar{Z}^T H \bar{Z}$ , implies that v and  $\rho$  can be calculated by

$$R^T v = Z^T H z$$
 and  $\rho^2 = z^T H z - v^T v$ . (2.16)

On the other hand, deleting a superbasic variable is equivalent to removing a row and column from R. The relevant column of R is removed and the remaining columns are permuted forward. A forward sweep of plane rotations is then used to restore R to upper-triangular form.

Deleting a basic variable is more complicated because it first requires swapping a column of B with a column of S. This process is sometimes referred to as a BS swap. If the p-th column of B is being moved to N, let the vector y satisfy  $y = S^T w$  for  $B^T w = e_p$ . The elements  $(y)_j$  can be thought of as the pivot elements that would arise if the j-th column of S were selected for the basis change. The q-th superbasic could be selected such that  $|(y)_q| = y_{max} = \max_j |(y)_j|$ . If  $y_{max}$  were at, or very near one of its bounds, another BS swap update might be required in only a few iterations. Since the BS swap requires extra work for an associated update to R (see Lemma 1), this condition is relaxed. Let Q be the set of superbasic variables associated with elements of y of sufficient magnitude, defined by

$$Q = \{ j \mid |(y)_j| \ge \theta |y_{max}| \},$$

where  $0 < \theta < 1$ . The p-th basic variable is swapped with the q-th superbasic, where q is chosen by

$$\{ q \mid \nu_q = \max_{j \in \mathcal{Q}} \{\nu_j\} \}. \tag{2.17}$$

with  $\nu_j = \min\{ |(x,s)_j - l_j|, |(x,s)_j - u_j| \}$ . This method of selecting the superbasic variable for the BS swap is the same as that used in MINOS [30].

The matrix R must be updated to reflect the swap. The update to R for the BS swap uses the following result, due to Murtaugh and Saunders [30]. This proof, which has not appeared elsewhere, is included for completeness.

**Lemma 1** Let Z be as in (2.10), with  $B \in \mathbb{R}^{m \times m}$  nonsingular and  $S \in \mathbb{R}^{m \times n_s}$ ; and R be upper-triangular with  $R^TR = Z^THZ$ . If the p-th column of B and the q-th column of S are swapped, let  $y = S^Tw$ ,  $B^Tw = e_p$ , assume  $y \neq 0$ . Then the update to R is given by

$$\bar{R} = R - \frac{1}{(y)_q} r_q (y + e_q)^T,$$
 (2.18)

where  $(y)_q$  is the q-th element of y and  $r_q$  is the q-th column of R.

**Proof.** Let P be the permutation matrix used to define Z in (2.10). Define

$$Q = P \begin{pmatrix} -B^{-1}S & B^{-1} & 0 \\ I_S & 0 & 0 \\ 0 & 0 & I_N \end{pmatrix} = \begin{pmatrix} Z & Y & I_* \end{pmatrix},$$

so that

$$Q^{-1} = \begin{pmatrix} 0 & I_S & 0 \\ B & S & 0 \\ 0 & 0 & I_N \end{pmatrix} P^T.$$

Note that  $\bar{Q}^{-1}$  is just a column permutation of  $Q^{-1}$  after its q-th row is replaced by  $e_p^T$  to preserve  $I_s$ . Therefore,

$$\bar{Q}^{-1} = (Q^{-1} + e_q(e_p - e_{m+q})^T) \hat{P},$$

where post-multiplication by  $\hat{P}$  swaps columns p and (m+q). Then

$$\bar{Q}^{-1} = (I + e_q(e_p - e_{m+q})^T Q) Q^{-1} \hat{P}.$$

If y is the vector  $y = S^T w$ , where w the solution of  $B^T w = e_p$ , then

$$\bar{Q}^{-1} = (I + e_q v^T) Q^{-1} \hat{P}, \text{ where } v = \begin{pmatrix} -(y + e_q) \\ w \\ 0 \end{pmatrix}.$$

Since  $y \neq 0$  by assumption, it follows that  $(y)_q \neq 0$ . Therefore, the Sherman-Morrison-Woodbury formula may be applied to give

$$\bar{Q} = \hat{P}^T Q \left( I + \frac{1}{(y)_q} e_q v^T \right) \stackrel{\triangle}{=} \hat{P}^T Q M,$$

and it follows that

$$Q^{T}HQ = Q^{T}\hat{P}\hat{P}^{T}H\hat{P}\hat{P}^{T}Q = M^{-T}(\hat{P}\bar{Q})^{T}H(\hat{P}\bar{Q})M^{-1}.$$

If  $\bar{Q}$  is assumed to include the permutation  $\hat{P}$ , so that  $\bar{Q} = \hat{P}\bar{Q}$ , then  $\bar{Q}^T H \bar{Q} = M^T Q^T H Q M$ . Since  $R^T R = Z^T H Z$  and

$$Q^{T}HQ = \begin{pmatrix} Z^{T}HZ & Z^{T}HY & Z^{T}HI_{*} \\ Y^{T}HZ & Y^{T}HY & Y^{T}HI_{*} \\ I_{*}^{T}HZ & I_{*}^{T}HY & I_{*}^{T}HI_{*} \end{pmatrix},$$

if  $M_S$  denotes the leading principal submatrix of M, then

$$M_{S} = I_{S} - \frac{1}{(y)_{q}} e_{q} (y + e_{q})^{T},$$

and

$$\bar{R} = RM_S = R - \frac{1}{(y)_q} r_q (y + e_q)^T,$$

where  $(y)_q$  is the q-th element of y and  $r_q$  is the q-th column of R.

After R is updated via (2.18), R is restored to upper-triangular form using two sweeps of plane rotations. Once the BS swap is complete, the "new" p-th column of S is moved to N by updating  $\bar{R}$  as described above for deleting a superbasic variable.

The implementation of SQOPT stores only the non-zero entries of R, thus the procedures for updating R are done in place, using the minimum extra work space necessary.

## 2.3.4 Algorithm SQOPT

The following pseudo-code description of Algorithm SQOPT is presented to help clarify the preceding discussion and to provide a reference for the algorithms presented in *Chapter 3* and *Chapter 4*. While this chapter provides the details needed in the development of these algorithms, it is not intended to be a complete description of SQOPT. For a more complete description of SQOPT, see [15].

## Algorithm 2.3.1. SQOPT

```
Find a feasible point, (x, s)
Factorize the initial reduced Hessian R^T R = Z^T H Z
Calculate the initial g and \psi
while true
   Calculate multipliers \pi and g_z = Z^T g
    stationary-point = ||g_z|| < \mathtt{RGTOL}
    new-SB = \mathbf{false}
    if stationary-point then
         Calculate multipliers, \lambda
         Check (\pi, \lambda) for optimality and set optimal
         if optimal then
              stop
         else
              Select new superbasic
              new-SB = true
         end if
    end if
    if new-SB then
         Update R and g_z
    end if
    Compute p_z to satisfy (2.13) or (2.14)
    \alpha_N = \text{maximum feasible step along } p
    if R is nonsingular then
         hit-constraint = \alpha_N < 1
    else
         hit-constraint = \alpha_N < \infty
         if not hit-constraint then stop
    end if
    if hit-constraint then
         \alpha = \alpha_N
    \mathbf{else}
         \alpha = 1
   end if
   (x,s) \leftarrow (x,s) + \alpha p
```

```
g \leftarrow g + \alpha H p
Calculate \psi
if hit-constraint then
Update R
end if
end while
```

When a superbasic is added,  $g_z$  is updated by adding the element corresponding to  $z^T g$ , where z is defined by (2.15). If  $\lambda_q$  is the multiplier for the new superbasic, then it follows from (2.12) that  $z^T g = \lambda_q$  and

$$ar{g}_Z = \left(egin{array}{c} g_Z \ \lambda_q \end{array}
ight).$$

For details on calculating a descent direction with zero curvature to satisfy (2.14) when R is singular, see [15].

The reduced gradient tolerance, RGTOL, is used to determine convergence on the current subspace of active constraints. The value of RGTOL is typically  $10^{-6}$ .

The reduced-Hessian QP algorithm presented in *Chapter 3* is derived directly from SQOPT. In contrast, the Schur-complement QP algorithm of *Chapter 4* is a distinctly different algorithm, however, it does generate the same search directions as SQOPT.

# Chapter 3

# The Conjugate-Gradient Method

A well known approach for solving a large symmetric positive-definite linear system Cx = f, without factoring C, is the conjugate-gradient method of Hestenes and Stiefel [26] (see also [10, 14, 25, 31]). The conjugate-gradient method is an iterative method based on a five-term recurrence relation (see below). The method proposed in this chapter is based on using a conjugate-gradient algorithm to solve the reduced-Hessian systems,  $H_z p_z = -g_z$ .

A conjugate-gradient method generates a sequence of search directions that are mutually conjugate with respect to C. The conjugate-gradient method exhibits finite termination in exact arithmetic; in particular, if C has  $n_e$  distinct eigenvalues, then at most  $n_e$  iterations are required for convergence. Although, the CG method was originally conceived as an exact method, in practice, rounding errors degrade the numerical conjugacy of the search directions and convergence is characteristic of an iterative method.

The conjugate-gradient method works much better on systems that have only a few distinct eigenvalues, or clustered eigenvalues [27]. As a consequence, a common practice is to precondition the linear system to accelerate the convergence. Preconditioning involves applying CG to a transformed system that has a more favorable eigenvalue distribution (see below).

# 3.1 Linear Systems and Least-Squares Problems

Consider applying the conjugate-gradient (CG) method to the system

$$Cx = f, (3.1)$$

where C is symmetric and positive definite. Given  $x_k$ ,  $\beta_{k-1}$  and  $d_{k-1}$ , a CG iteration is defined by

$$d_{k} = -r_{k} + \beta_{k-1}d_{k-1},$$

$$\alpha_{k} = \frac{\|r_{k}\|^{2}}{d_{k}^{T}Cd_{k}},$$

$$x_{k+1} = x_{k} + \alpha_{k}d_{k},$$

$$r_{k+1} = r_{k} + \alpha_{k}Cd_{k},$$

$$\beta_{k} = \frac{\|r_{k+1}\|^{2}}{\|r_{k}\|^{2}}.$$
(3.2)

For the first iteration,  $\beta_{-1} = 0$  and  $d_{-1} = 0$ . The iterates  $\{x_k\}$  are approximations to the solution, and the search directions  $\{d_k\}$  are such that  $d_iCd_j = 0$  for  $i \neq j$ . The residual at each  $x_k$  is given by  $r_k = Cx_k - f$ . Note that the CG method only uses C as part of a matrix-vector product.

Suppose  $C = A^T A$  for some  $A \in \mathbb{R}^{m \times n}$ , where  $m \geq n$  and  $\operatorname{rank}(A) = n$ . Similarly, let  $f = A^T b$  for some b. In this case, the original system Cx = f is equivalent to

$$A^T A x = A^T b. (3.3)$$

These are the normal equations for the least-squares (LS) problem

$$\min \|b - Ax\|^2. \tag{3.4}$$

It follows that the solution of (3.1) can be found by solving (3.4). In this case, the solution x can be found using the least-squares CG algorithm LSQR [32] on (3.4). LSQR requires matrix-vector products of the form Av and  $A^Tu$ , instead of the  $A^TAv$  form required by a general symmetric CG algorithm.

The sensitivity of least-squares solutions to perturbations in A and b are summarized in the following theorem. Define  $\kappa(A)$  to be the spectral condition number

of A given by  $\kappa(A) = ||A|| ||A^+||$ , where  $A^+$  is the pseudo-inverse of A. If A has full rank with  $m \ge n$ ,  $A^+ = (A^T A)^{-1} A^T$ .

**Theorem 1** Let  $x = \arg \min \|Ax - b\|^2$  and  $\hat{x} = \arg \min \|(A + \delta A)\hat{x} - (b + \delta b)\|$ , where A and  $\delta A$  are in  $\mathbb{R}^{m \times n}$  with  $m \geq n$  and  $0 \neq b$  and  $\delta b$  are in  $\mathbb{R}^m$ . Furthermore, let r and  $\hat{r}$  be the residuals associated with x and  $\hat{x}$  respectively. If

$$\epsilon = \max\left\{\frac{\|\delta A\|}{\|A\|}, \frac{\|\delta b\|}{\|b\|}\right\} < \frac{1}{\kappa(A)}$$

and  $\sin \theta = \rho/\|b\| \neq 1$ , where  $\rho = \|Ax - b\|$ , then

$$\frac{\|\widehat{x} - x\|}{\|x\|} \le \epsilon \left\{ \frac{2\kappa(A)}{\cos \theta} + \tan \theta \kappa(A)^2 \right\} + \mathcal{O}(\epsilon^2), \tag{3.5}$$

$$\frac{\|\widehat{r} - r\|}{\|b\|} \le \epsilon \left(1 + 2\kappa(A)\right) \min(1, m - n) + \mathcal{O}(\epsilon^2). \tag{3.6}$$

**Proof.** See Golub and Van Loan [24].

Golub and Van Loan show that

$$\tan \theta = \rho / \sqrt{\|b\|^2 - \rho^2},$$

therefore, it follows from Theorem 1 that the sensitivity of the LS solution is proportional to  $\kappa(A) + \rho \kappa(A)^2$ . When Ax = b is incompatible, the sensitivity is dominated by  $\kappa(A)^2$  if  $\rho$  is not close to zero. The condition number of C is  $\kappa(C) = \kappa(A^T A) = \kappa(A)^2$ . Thus, it follows that the sensitivity of solutions of Cx = d, and the least-squares problem (3.4), are both proportional to  $\kappa(C)$ . Therefore, if  $C = A^T A$  and  $f = A^T b$ , the relative accuracy of the solutions from the CG algorithm for (3.1) and from LSQR for (3.4) will be comparable, but products of the form  $A^T Av$  are avoided.

Solving the reduced-Hessian system  $H_z p_z = -g_z$  using the CG method requires forming matrix-vector products of the form  $H_z u = Z^T H Z u$ . Since both H and Z are available implicitly, a symmetric linear CG algorithm such as SYMMLQ [31] can be used. However, by using a CG algorithm based on a least-squares formulation we benefit from the numerical advantages discussed in [32].

## 3.2 Background on LSQR

Algorithm LSQR is equivalent to the CG method in exact arithmetic. However, in the least-squares context, LSQR has been shown to be more reliable than standard CG methods. In Paige and Saunders [32], the authors point out that the least-squares adaptation of symmetric CG is always more reliable than applying the symmetric CG algorithm to the normal equations. In addition, they show that when A is ill-conditioned, LSQR should be more reliable than other least-squares CG algorithms such as CGLS [3].

The algorithm LSQR is based on the bidiagonalization routine of Golub and Kahan [23]. This procedure generates a set of vectors  $\{u_i, v_i\}$  using the following algorithm.

#### Algorithm 3.2.1. BIDIAG

$$eta_1 u_1 = b$$
  $lpha_1 v_1 = A^T u_1$  for  $i = 1, 2, \dots$   $eta_{i+1} u_{i+1} = A v_i - lpha_i u_i$   $lpha_{i+1} v_{i+1} = A^T u_{i+1} - eta_{i+1} v_i$  end

The scalars  $\alpha_i \geq 0$  and  $\beta_i \geq 0$  are chosen so that  $||u_i|| = ||v_i|| = 1$ . By defining

$$U_{k} \equiv (u_{1}, u_{2}, \dots, u_{k}),$$

$$V_{k} \equiv (v_{1}, v_{2}, \dots, v_{k}),$$

$$B_{k} \equiv \begin{pmatrix} \alpha_{1} & & & \\ \beta_{2} & \alpha_{2} & & & \\ & \beta_{3} & \ddots & & \\ & & \ddots & \alpha_{k} & \\ & & & \beta_{k+1} \end{pmatrix}, \quad (3.7)$$

the recurrence relations of BIDIAG may be written in matrix form as

$$U_{k+1}(\beta_1 e_1) = b, (3.8)$$

$$AV_k = U_{k+1}B_k, (3.9)$$

$$A^{T}U_{k+1} = V_{k}B_{k}^{T} + \alpha_{k+1}v_{k+1}e_{k+1}^{T}.$$
(3.10)

In exact arithmetic,  $U_{k+1}^T U_{k+1} = I$  and  $V_{k+1}^T V_{k+1} = I$ .

LSQR uses the quantities generated by BIDIAG to solve the LS problem (3.4). Let  $x_k$ ,  $r_k$  and  $t_{k+1}$  be defined by

$$x_k = V_k y_k, \tag{3.11}$$

$$r_k = b - Ax_k, (3.12)$$

$$t_{k+1} = \beta_1 e_1 - B_k y_k, \tag{3.13}$$

for some vector  $y_k$ . Using (3.8) and (3.9) it can be shown that

$$r_k = U_{k+1} t_{k+1}.$$

The quantity  $||r_k||$  can be minimized by choosing  $y_k$  to minimize  $||t_k||$ , i.e., by defining  $y_k$  as the solution of

$$\min \|\beta_1 e_1 - B_k y_k\|. \tag{3.14}$$

The LSQR algorithm is derived by using the standard QR decomposition of  $B_k$  to solve (3.14).

# 3.3 Defining the Least-Squares Problem

In the SQP method considered here, the matrix  $H_k$  of the k-th QP subproblem (1.2) is a limited-memory quasi-Newton approximation to the Lagrangian Hessian. The updating scheme for  $H_k$  described in Section 2.1.3 is based on the BFGS update. The product form of the BFGS update for  $H_k$  is given by

$$H_{k+1} = (I + v_k u_k^T) H_k (I + u_k v_k^T), \tag{3.15}$$

where

$$u_k = \frac{1}{\|H_k s_k\|} s_k$$
 and  $v_k = \frac{1}{\sqrt{y_k^T s_k}} y_k - \frac{1}{\|H_k s_k\|} H_k s_k$ .

Here,  $s_k$  is the change in the position vector and  $y_k$  is the corresponding change in the gradient vector. By modifying the updating scheme used for  $H_k$  according to (3.15), a matrix  $G_k$  can be defined such that  $H_k = G_k^T G_k$ . This alternative limited-memory scheme stores the update vectors for  $G_k$ . The update vectors  $u_k$ and  $v_k$  are given by

$$u_k = \frac{1}{\|G_k \delta_k\|} \delta_k$$
 and  $v_k = \frac{1}{\sqrt{y_k^T \delta_k}} y_k - \frac{1}{\|G_k \delta_k\|} G_k^T G_k \delta_k$ ,

where  $\delta_k$  and  $y_k$  are defined by (2.4). Each update to  $G_k$  is defined by  $G_{k+1} = G_k(I + u_k v_k^T)$ , which implies

$$G_{k+1} = G_r(I + u_r v_r^T)(I + u_{r+1} v_{r+1}^T) \cdots (I + u_k v_k^T) = G_r \prod_{i=r}^k (I + u_i v_i^T),$$

where the nonsingular  $G_r$  is defined by  $G_r^T G_r = H_r$ , for the  $H_r$  described in Section 2.1.3.

This limited-memory scheme easily allows for the formation of matrix-vector products with the current  $G_k$ ; in particular, a product of the form  $w = G_k z$  can be computed using the following algorithm.

**Algorithm 3.3.1.** (Computation of  $w = G_k z$ )

w = z

for 
$$i = k - 1 : -1 : r$$
  

$$w = w + (v_i^T w)u_i$$

end

$$w = G_r w$$

A similar loop can be defined for computing  $w = G_k^T z$ . In addition, by proper application of the Sherman-Morrison-Woodbury formula,  $G_k^{-T}$  is given by

$$G_k^{-T} = G_r^{-1} \prod_{i=r}^{k-1} (I - \frac{1}{1 + u_i^T v_i} v_i u_i^T).$$

The solution of systems with  $G_k^T$  can be obtained by computing  $w = G_k^{-T}z$  using the following algorithm.

**Algorithm 3.3.2.** (Computation of  $w = G_k^{-T} z$ )

w = z

for 
$$i = k - 1 : -1 : r$$
  
 $w = w - (u_i^T w)/(1 + u_i^T v_i)v_i$ 

end

$$w = G_r^{-1} w$$

The work required for computing  $w = G_k z$  or  $w = G_k^T z$  is n(k-r+1) + (k-r) flops, while solving  $G_k^T w = z$  requires (2n+1)(k-r) + 2(k-r) flops and one division.

The subscript k is now dropped from the relevant quantities since only a single subproblem is being considered. The direction  $p_z$  can be found by using LSQR to solve the LS problem (3.4) for the appropriate A and b. Let A and b be defined by

$$A = GZ \quad \text{and} \quad b = G^{-T}g, \tag{3.16}$$

where g is the current QP gradient. Then the modified reduced-Hessian system,  $Z^TG^TGZp_Z = Z^Tg$ , are the normal equations for the least-squares problem (3.4). If x is the solution to problem (3.4), then  $p_Z = -x$ .

For the definition given (3.16),  $A \in \mathbb{R}^{n \times n_s}$ , with  $n > n_s$  and rank $(A) = n_s$ . In addition, the system Ax = b is usually incompatible, i.e.,  $\rho \neq 0$ . Thus, the sensitivity analysis is similar to that discussed in Section 3.1. The following lemma corresponds to Theorem 1 with a perturbation to A = GZ of the form  $\delta A = G\delta Z$ .

**Lemma 2** Let  $x = \arg \min \|GZx - G^{-T}g\|^2$  and  $\hat{x} = \arg \min \|G(Z + \delta Z)\hat{x} - G^{-T}(g + \delta g)\|$ , where Z and  $\delta Z$  are in  $\mathbb{R}^{n \times n_s}$  with  $n \geq n_s$  and  $0 \neq g$  and  $\delta g$  are in  $\mathbb{R}^n$ . Furthermore, let r and  $\hat{r}$  be the residuals associated with x and  $\hat{x}$  respectively. If

$$\epsilon = \max \left\{ \frac{\|G\delta Z\|}{\|GZ\|}, \frac{\|G^{-T}\delta g\|}{\|G^{-T}g\|} \right\} < \frac{\sigma_n(GZ)}{\sigma_1(GZ)}$$

and, assuming  $\|G^{-T}h\| \le \|G^{-T}g\|$  and  $\sin \theta = \rho/\|G^{-T}g\| \ne 1$ , where  $\rho = \|GZx - G\|$ 

 $G^{-T}g \parallel$ , then

$$\frac{\|\widehat{x} - x\|}{\|x\|} \le \epsilon \left\{ \frac{\kappa(GZ)}{\cos \theta} (1 + \gamma \cos \theta) + \gamma \tan \theta \kappa(GZ)^2 \right\} + \mathcal{O}(\epsilon^2), \quad (3.17)$$

$$\frac{\|\widehat{r} - r\|}{\|G^{-T}g\|} \le \epsilon \left(1 + 2\gamma\kappa(A)\right) \min(1, m - n) + \mathcal{O}(\epsilon^2),\tag{3.18}$$

where

$$\gamma = \frac{\|G\| \|Z\|}{\|GZ\|}.$$

**Proof.** The proof follows that of Theorem 1 from Golub and Van Loan [24]. Let E and h be defined by  $E = \delta Z/\epsilon$  and  $h = \delta g/\epsilon$ . Since  $||G\delta Z|| < \sigma_n(GZ)$  by assumption, it can be shown that  $\operatorname{rank}(GZ + GEt) = n_s$  for all  $t \in [0, \epsilon]$ . Thus, the solution x(t) such that

$$(Z + Et)^T G^T G(Z + Et)x(t) = (Z + Et)^T G^T G^{-T}(g + ht)$$
(3.19)

is continuously differentiable for all  $t \in [0, \epsilon]$ . Since x = x(0) and  $\hat{x} = x(\epsilon)$ , it follows that

$$\hat{x} = x + \epsilon \dot{x}(0) + \mathcal{O}(\epsilon^2).$$

The assumptions that  $g \neq 0$  and  $\sin \theta \neq 1$  ensure that x is nonzero, and hence

$$\frac{\|\hat{x} - x\|}{\|x\|} = \epsilon \frac{\|\dot{x}(0)\|}{\|x\|} + \mathcal{O}(\epsilon^2). \tag{3.20}$$

To obtain a bound for  $||\dot{x}(0)||$ , (3.19) can be differentiated, t set to zero and the equation solved for  $\dot{x}(0)$ . This gives

$$\dot{x}(0) = H_z^{-1} \{ Z^T G^T (G^{-T} h - GEx) + E^T G^T r \}.$$
 (3.21)

It can be shown that  $||E|| \le ||Z||$  and  $||h|| \le ||g||$ . Therefore, since  $||G^{-T}h|| \le ||G^{-T}g||$ , substituting (3.21) into (3.20) and taking norms yields

$$\frac{\|\widehat{x} - x\|}{\|x\|} \leq \epsilon \left\{ \|GZ\| \|H_z^{-1} (GZ)^T\| \left( \frac{\|G^{-T}g\|}{\|GZ\| \|x\|} + \gamma \right) + \gamma \rho \frac{\|H_z^{-1}\| \|GZ\|}{\|x\|} \right\} + \mathcal{O}(\epsilon^2).$$

The following relations are easily established using the definition of the pseudoinverse, and the singular values of GZ:

$$||GZ|| ||H_z^{-1}(GZ)^T|| = \kappa(GZ),$$
  
$$||GZ||^2 ||H_z^{-1}|| = \kappa(GZ)^2.$$
 (3.22)

In addition, since  $(GZ)^T(GZx-G^{-T}g)=0$ , it follows that GZx and  $GZx-G^{-T}g$  are orthogonal with

$$||GZ||^2 ||x||^2 \ge ||G^{-T}g||^2 - \rho^2.$$

Finally, using (3.22)

$$\frac{\|\widehat{x} - x\|}{\|x\|} \le \epsilon \left\{ \frac{\kappa(GZ)}{\cos \theta} (1 + \gamma \cos \theta) + \gamma \tan \theta \kappa(GZ)^2 \right\} + \mathcal{O}(\epsilon^2),$$

which proves (3.17).

To establish (3.18), define r(t) by the differentiable function

$$r(t) = G^{-T}(g + ht) - G(Z + Et)x(t).$$

Using (3.21), it can be shown that

$$\dot{r}(0) = (I - GZ(H_z^{-1})(GZ)^T)(G^{-T}h - GEx) - GZ(H_z^{-1})E^TG^Tr.$$

Noting that r = r(0) and  $\hat{r} = r(\epsilon)$ , and using  $\|\hat{r} - r\| = \epsilon \|\dot{r}(0)\| + \mathcal{O}(\epsilon^2)$ , yields

$$\frac{\|\hat{r} - r\|}{\|G^{-T}g\|} = \epsilon \frac{\|\dot{r}(0)\|}{\|G^{-T}g\|} + \mathcal{O}(\epsilon^{2})$$

$$\leq \epsilon \left\{ \|I - GZ(H_{z}^{-1})(GZ)^{T}\| \left(1 + \frac{\|G\|\|Z\|\|x\|}{\|G^{-T}g\|}\right) + \|GZ(H_{z}^{-1})\|\|G\|\|Z\| \frac{\rho}{\|G^{-T}g\|} \right\} + \mathcal{O}(\epsilon^{2}).$$

The inequality (3.18) follows from

$$||GZ|||x|| = ||GZ|||(GZ)^{+}G^{-T}g|| \le \kappa(GZ)||G^{-T}g||,$$

$$\rho = ||I - GZ(H_{z}^{-1})(GZ)^{T}G^{-T}g|| \le ||I - GZ(H_{z}^{-1})(GZ)^{T}||||G^{-T}g||,$$

and

$$||I - GZ(H_z^{-1})(GZ)^T|| = \min(m - n, 1).$$

The implication of this result is that the sensitivity of the LS problem with A = GZ is proportional to  $\gamma(\kappa(GZ) + \kappa(GZ)^2)$ . Thus, the appearance of G has the effect of increasing the sensitivity by the factor  $\gamma \geq 1$ .

Each iteration of LSQR for solving (3.4) will require matrix-vector products involving GZ and  $(GZ)^T$ . In addition, forming the right-hand side requires the solution of a system with  $G^T$ . The modified updating scheme for H allows for the formation of matrix-vector products with G,  $G^T$  and  $G^{-T}$ . In addition, calculating matrix-vector products with Z and  $Z^T$  can be done using the implicit form given in Section 2.2.

If there are linear variables, then H is positive semidefinite and has the form (2.6) (see Section 2.1.2). This type of structural singularity can be handled by solving the reduced-Hessian system as a damped least-squares problem. In the linear variable case, H is given by

$$H = \left( \begin{array}{c} G^T G \\ 0 \end{array} \right),$$

where G is defined by the modified updating scheme for H. Let H be approximated by

$$H pprox \left( egin{array}{cc} G^T G & & \ & & \ & & \sigma^2 I \end{array} 
ight),$$

for some small positive  $\sigma$ . The direction  $p_z$  can be found by using LSQR to solve the damped LS problem of the form (3.4), where

$$A = \begin{pmatrix} G \\ & \sigma I \end{pmatrix} Z$$
 and  $b = \begin{pmatrix} G^{-T} \\ & \sigma^{-1} I \end{pmatrix} g$ .

# 3.4 Preconditioning the Least-Squares System

The convergence of the CG algorithm resulting from the recurrence relations (3.2) can be characterized by the following theorems.

**Theorem 2** If C = I + B is an  $n \times n$  symmetric positive-definite matrix and rank(B) = r, then the CG algorithm applied to Cx = f converges in at most r + 1 steps.

#### **Proof.** See Golub and Van Loan [24].

This result can be used to show that if C has  $n_e$  distinct eigenvalues, then the CG algorithm will require at most  $n_e$  steps.

The second theorem shows that the CG algorithm will converge more rapidly when C is well conditioned, or has clustered eigenvalues. The theorem is stated in terms of the elliptic norm

$$||w||_C = \sqrt{w^T C w}.$$

**Theorem 3** Suppose  $C \in \mathbb{R}^{n \times n}$  is symmetric positive-definite and  $d \in \mathbb{R}^n$ . If the CG algorithm applied to Cx = f produces iterates  $\{x_k\}$  and  $\kappa(C) = \|C\| \|C^{-1}\|$ , then

$$||x - x_k||_C \le 2||x - x_0||_C \left(\frac{\sqrt{\kappa(C)} - 1}{\sqrt{\kappa(C)} + 1}\right).$$

### **Proof.** See Luenberger [28].

The intent of preconditioning is to transform the original system to one that exploits the convergence properties of the CG algorithm. Let M be a nonsingular preconditioner for the system Cx = f. The preconditioned matrix  $M^{-T}CM^{-1}$  will have fewer distinct eigenvalues than C, or its eigenvalues will exhibit better clustering than those of C.

The term exact preconditioner is often used in the context of CG methods. Loosely speaking, an exact preconditioner is one that gives a preconditioned system with a block of unit eigenvalues. For example,  $M = C^{-\frac{1}{2}}$  is an exact preconditioner since the preconditioned system is the identity.

In either case, applying CG to the preconditioned system  $M^{-T}CM^{-1}y = M^{-T}f$  may be preferable to solving Cx = f directly. The solution x can be obtained from y by solving Mx = y. For  $y_0 = Mx_0$  and  $r_0 = M^{-T}CM^{-1}y_0 - M^{-T}f$  (and again  $\beta_{-1} = 0$  and  $d_{-1} = 0$ ), the preconditioned CG method can be defined for  $k = 0, 1, 2, \ldots$  as

$$d_{k} = -r_{k} + \beta_{k-1}d_{k-1};$$

$$\alpha_{k} = \frac{r_{k}^{T}r_{k}}{d_{k}^{T}(M^{-T}CM^{-1})d_{k}};$$

$$y_{k+1} = y_{k} + \alpha_{k}d_{k};$$

$$r_{k+1} = r_{k} + \alpha_{k}(M^{-T}CM^{-1})d_{k};$$

$$\beta_{k} = \frac{\|r_{k+1}\|_{2}^{2}}{\|r_{k}\|_{2}^{2}},$$

and  $x_k$  is the solution of  $Mx_k = y_k$ . Note that the preconditioned iterations require additional solves with M. Thus, M must be such that systems of the form Mx = y can be solved efficiently. For example, M could be a diagonal or triangular matrix.

If  $C = A^T A$  and  $d = A^T b$ , then x can be obtained by using LSQR to solve the preconditioned least-squares problem

minimize 
$$||b - AM^{-1}y||$$
. (3.23)

The basis for the CG method is to use LSQR to solve (3.23) when A and b are defined as in (3.16), and M is one of two different preconditioners investigated in Sections 3.5 and 3.6.

The first preconditioner involves calculating the Cholesky factor  $R_r$  of the  $n_r \times n_r$  leading principal submatrix of the reduced Hessian, denoted by  $Z_r^T H Z_r$ . This preconditioner is of the form

$$R_C = \left(\begin{array}{cc} R_r & 0\\ 0 & D \end{array}\right),\,$$

where D is a positive-definite diagonal extension. The second preconditioner involves using  $R_C$  with quasi-Newton approximations to  $R_r$  and D.

Although  $R_r^T R_r = Z_r^T H Z_r$ , neither preconditioner is exact. Let the R such that  $R^T R = Z^T H Z$  be partitioned by

$$R = \begin{pmatrix} R_r & R_{rs} \\ & R_s \end{pmatrix}, \tag{3.24}$$

where,  $R_r \in \mathbb{R}^{n_r \times n_r}$ ,  $R_{rs} \in \mathbb{R}^{n_r \times (n_s - n_r)}$  and  $R_s \in \mathbb{R}^{(n_s - n_r) \times (n_s - n_r)}$ . The following result shows that both  $R_r$  and  $R_{rs}$  are required for a block preconditioner based on R to be exact.

**Theorem 4** Let R be as in (3.24) and let A be defined as in (3.16). If

$$M = \begin{pmatrix} R_r & R_{rs} \\ & D \end{pmatrix},$$

where D is positive-definite, then the preconditioned matrix  $M^{-T}A^{T}AM^{-1}$  has at least  $n_r$  unit eigenvalues.

**Proof.** Let Z by partitioned as  $Z = (Z_r - Z_s)$ , where  $Z_r$  has  $n_r$  columns and  $Z_s$  has  $n_s - n_r$  columns. This defines a corresponding block partition of the reduced Hessian, given by

$$Z^{T}HZ = \begin{pmatrix} Z_r^{T}HZ_r & Z_r^{T}HZ_s \\ Z_s^{T}HZ_r & Z_s^{T}HZ_s \end{pmatrix}.$$
(3.25)

From  $R^T R = Z^T H Z$ , and substituting from (3.25), it follows that

$$R^{-T} \begin{pmatrix} Z_r^T H Z_r & Z_r^T H Z_s \\ Z_s^T H Z_r & Z_s^T H Z_s \end{pmatrix} R^{-1} = \begin{pmatrix} I_{n_r} & 0 \\ 0 & I_{(n_s - n_r)} \end{pmatrix}, \tag{3.26}$$

for

$$R^{-1} = \begin{pmatrix} R_r^{-1} & -R_r^{-1}R_{rs}R_s^{-1} \\ & & \\ & & R_s^{-1} \end{pmatrix}.$$

Computing both sides of (3.26) and comparing the one-one block, and the off-diagonal blocks, yields

$$R_r^{-T} Z_r^T H Z_r R_r^{-1} = I, (3.27)$$

$$R_{rs} = R_r^{-T} (Z_r^T H Z_s). (3.28)$$

It follows from (3.16) that  $A^T A = Z^T H Z$ . Thus, with

$$M^{-1} = \begin{pmatrix} R_r^{-1} & -R_r^{-1}R_{rs}D^{-1} \\ 0 & D^{-1} \end{pmatrix},$$

 $M^{-T}A^{T}AM^{-1}$  reduces to

$$\begin{pmatrix}
R_r^{-T}(Z_r^T H Z_r) R_r^{-1} & -R_{rs} D^{-1} + R_r^{-T}(Z_r^T H Z_s) D^{-1} \\
-D^{-T} R_{rs} + D^{-T}(Z_s^T H Z_r) R_r^{-1} & D^{-T}(Z_s^T H Z_s - R_{rs}^T R_{rs}) D^{-1}
\end{pmatrix}.$$
(3.29)

Using (3.27) and (3.28), it follows that

$$M^{-T}A^TAM^{-1} = \begin{pmatrix} I_{n_r} & 0\\ 0 & B \end{pmatrix},$$

where B is the (2,2) block of (3.29).

While the efficiency of an exact preconditioner would be beneficial,  $R_{rs}$  is a  $n_r \times (n_s - n_r)$  dense matrix. Since the dimension  $n_r$  is of moderate size, for problems where  $n_s$  is large, the column dimension  $n_s - n_r$  will be large as well. Thus, the expense of computing and maintaining  $R_{rs}$  is prohibitive. Therefore, using  $R_C$  as a preconditioner will not yield a system with  $n_r$  unit eigenvalues, but it is expected that the eigenvalues of the preconditioned system will be more clustered than those of  $H_Z$ .

# 3.5 The Partial Reduced-Hessian Preconditioner

The first preconditioner to be investigated has block diagonal structure

$$R_C = \left(\begin{array}{cc} R_r & 0\\ 0 & D \end{array}\right),\,$$

with  $R_r$  the Cholesky factor of  $Z_r^T H Z_r$ , the  $n_r \times n_r$  leading principal submatrix of the reduced Hessian. The matrix D is a positive diagonal matrix whose elements approximate the associated diagonal elements of the Cholesky factor of the full reduced Hessian.

After each QP search direction is calculated and a step taken, the preconditioner  $R_C$  must be updated to reflect changes to the working set. When the working set changes, the strategy for updating  $R_C$  is to maintain  $R_r$  as the Cholesky factor of the current  $Z_r^T H Z_r$ . The two possible changes to the working set correspond to the three updates discussed in Section 2.3.3; adding a superbasic variable, deleting a superbasic variable or deleting a basic variable.

### 3.5.1 Adding a Superbasic Variable

When a superbasic variable is added, the row and column associated with the new superbasic are added to  $R_r$ . Let  $g_z$  be partitioned as  $g_z = (g_1 \ g_2)^T$ , where  $g_1 \in \mathbb{R}^{n_r}$  corresponds to the variables that define  $R_r$ . The expectation is that as the QP algorithm reduces the norm of the reduced gradient, the reduction in the magnitude of the elements of  $g_1$  associated with  $R_r$  will be greater than the corresponding reduction in the elements of  $g_2$  associated with D. By including the new superbasic with the variables defining the dense upper-triangular block, the aim is to emphasize the reduction of the component of the reduced gradient associated with the new variable. Since the dimension of  $R_r$  is fixed, one of the variables already associated with  $R_r$  must be moved to D. The q-th superbasic is moved, where q is chosen to correspond to the smallest element in magnitude of  $g_1$ ; i.e.,

$${q \mid |(Z^T g)_q| \le |(Z^T g)_j|, 1 \le j \le n_r}.$$
 (3.30)

The q-th diagonal of  $R_r$  is added to the end of the diagonal matrix D, so that

$$ar{D} = \left( egin{array}{cc} D & 0 \\ 0 & r_{qq} \end{array} 
ight).$$

The q-th column of  $R_r$  is then deleted using the algorithm for deleting a superbasic from the Cholesky factor of the full reduced Hessian. Columns q+1 through  $n_r$  are then cyclicly permuted forward, and a sweep of plane rotations are applied to restore  $R_r$  to upper-triangular form. After the plane rotations have been applied, the last row and column of  $R_r$  are zero. Let  $\hat{R}_r$  be the  $(n_r - 1) \times (n_r - 1)$ upper-triangular submatrix of  $R_r$  without the zero row and column.

The calculation of the new column of  $R_r$  requires first partitioning S as  $S = (S_1 \quad S_2)$ , where  $S_1$  is the first  $n_r$  columns of S and  $S_2$  the remaining  $n_s - n_r$  columns. After updating D and deleting the q-th column from  $R_r$ , the updated S is given by

$$\bar{S} = (\bar{S}_1 \quad s_{n_r} \quad \bar{S}_2),$$

where  $s_{n_r}$  is the new column of S. The matrix  $\bar{S}_1$  results from deleting the q-th column of  $S_1$ , and the updated  $\bar{S}_2$  is the result of adding this column to the end of  $S_2$ . The new Z is given by

$$\bar{Z} = \begin{pmatrix} -B^{-1}\bar{S} \\ I \\ 0 \end{pmatrix} = \begin{pmatrix} -B^{-1}\bar{S}_1 & -B^{-1}s_{n_r} & -B^{-1}\bar{S}_2 \\ \tilde{I} & e_{n_r} & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} = (\bar{Z}_1 \ w \ \bar{Z}_2).$$

where  $\tilde{I}$  is an identity matrix of dimension  $n_r - 1$  augmented by a row of zeros. The update to  $R_r$  is given by

$$\bar{R}_r = \left(\begin{array}{cc} \hat{R}_r & v \\ 0 & \rho \end{array}\right),$$

where the new column of  $R_r$  is calculated from

$$\hat{R}_r^T v = \bar{Z}_1^T H w \qquad \text{and} \qquad \rho^2 = w^T H w - v^T v. \tag{3.31}$$

The work for calculating the new column is dominated by the cost of forming the right-hand side,  $\bar{Z}_1^T H w$ . From the discussions in Section 2.2 on Z, and Section 3.3 on  $H = G^T G$ , it easily follows that the work required to form the right-hand side

is at most  $m^2 + mn_r + 2nN$  flops. Here, N is the maximum number of limited-memory quasi-Newton updates before a reset. The work estimates are based on using an LU factorization of the matrix B to form products with Z. When a sparse LU factorization is used, there is a corresponding reduction in the work.

Finally, the update to the full  $R_C$  is

$$\bar{R}_C = \begin{pmatrix} \bar{R}_r & 0\\ 0 & \bar{D} \end{pmatrix}. \tag{3.32}$$

### 3.5.2 Deleting a Superbasic Variable

The method for deleting a superbasic variable depends on whether or not the variable is associated with  $R_r$  or D. If the q-th superbasic variable is to be deleted and  $q \leq n_r$ , then the q-th column of  $R_r$  is deleted in the same manner a column is deleted to make room for a new superbasic. The submatrix  $\hat{R}_r$  of the modified  $R_r$  is defined as above.

To maintain  $R_r$  as a  $n_r \times n_r$  matrix, a variable currently associated with D must be moved to  $R_r$ . The index of a superbasic variable associated with D is chosen by

$$\{t \mid |(Z^T g)_t| \ge |(Z^T g)_j|, n_r + 1 \le j \le n_s\}.$$
 (3.33)

This corresponds to selecting the variable associated with the element of largest magnitude in  $g_2$ . The update to S is given by

$$\bar{S} = (\bar{S}_1 \quad s_t \quad \bar{S}_2),$$

where  $s_t$  was the t-th column of S. The updated  $\bar{S}_1$  results from deleting the q-th column of  $S_1$ , and the matrix  $\bar{S}_2$  is the result of deleting  $s_t$  from  $S_2$ . Then,

$$\bar{Z}_1 = \begin{pmatrix} -B^{-1}\bar{S}_1\\ \tilde{I}\\ 0 \end{pmatrix} \quad \text{and} \quad w = \begin{pmatrix} -B^{-1}s_t\\ e_{n_r}\\ 0 \end{pmatrix}$$

yield

$$\bar{R}_r = \left(\begin{array}{cc} \hat{R}_r & v \\ 0 & \rho \end{array}\right),$$

where v and  $\rho$  are calculated as in (3.31). For  $D = \operatorname{diag}(d_1, ..., d_{n_s - n_r})$ , the updated  $\bar{D} = \operatorname{diag}(d_1, ..., d_{t-n_r-1}, d_{t-n_r+1}, ..., d_{n_s-n_r})$  and  $\bar{R}_C$  is given by (3.32). In this case, the work for deleting a superbasic is the same as for adding a superbasic, since in both cases a new column has to be computed for  $R_r$ .

When  $q > n_r$ , no update to  $R_r$  is needed since  $\bar{Z}_1^T H \bar{Z}_1 = Z_1^T H Z_1$ . Therefore,  $\bar{R}_r = R_r$  and  $\bar{D} = \text{diag}(d_1, ..., d_{q-n_r-1}, d_{q-n_r+1}, ..., d_{n_s-n_r})$ . Again,  $\bar{R}_C$  is given by (3.32).

### 3.5.3 Deleting a Basic Variable

Recall from Section 2.3.3 that deleting a basic variable corresponds to deleting a column of the basis matrix B. To maintain a nonsingular basis, an appropriate column of S is chosen to swap into B. The BS swap for  $R_C$  will depend on whether or not the superbasic to be swapped is associated with  $R_r$  or D. In contrast to the case where a superbasic is deleted, if the variable to be swapped is associated with D, there is a change to  $R_r$ . This is because the change to B affects both  $Z_1$  and  $Z_2$ , and  $\bar{Z}_1^T H \bar{Z}_1 \neq Z_1^T H Z_1$ .

Assume that the p-th basic variable is being deleted. Let  $y = S^T w$ , where  $B^T w = e_p$ . The q-th superbasic variable is selected for the BS swap by (2.17).

The BS swap update to R, the Cholesky factor of the reduced Hessian, is given by (2.18). The update can be stated in terms of y and R as

$$\bar{R} = R - U$$
 where  $U_{i,j} = \begin{cases} ((y)_j/(y)_q)R_{i,q} & i \le q, j \ne q \\ (((y)_q + 1)/(y)_q)R_{i,q} & i \le q, j \ne q \\ 0 & i > q \end{cases}$ 

This update requires knowledge of the nonzero entries of the q-th column of R, indicated by the elements  $R_{i,q}$  for  $i \leq q$ . If  $q \leq n_r$ , this column is well defined and

the update to  $R_r$  is given by

$$\bar{R}_r = R_r - \frac{1}{(y)_q} r_1 (y + e_q)^T,$$
 (3.34)

where  $r_1$  is the q-th column of  $R_r$ . The nonzero entries of  $r_1$  are identical to the nonzero entries of  $r_q$ , the q-th column of R. In this case, two sweeps of plane rotations restore  $\bar{R}_r$  to triangular form.

If  $q > n_r$ , however, some nonzero entries of  $r_q$  are not explicitly available. In this case, all that is required is to update  $R_r$  by

$$\bar{R}_r = R_r - \tilde{U},$$
 where  $\tilde{U}_{i,j} = \begin{cases} ((y)_j/(y)_q)R_{i,q}, & i \leq n_r; \\ 0, & i > n_r. \end{cases}$ 

Thus, only the first  $n_r$  elements of  $r_q$  are needed, which can be obtained from

$$R_r^T r_1 = Z_1^T H w$$
 where  $w = \begin{pmatrix} -B^{-1} s_q \\ e_q \\ 0 \end{pmatrix}$ ,

and  $s_q$  is the q-th column of S.

Once  $r_1$  has been obtained,  $R_r$  can be updated using (3.34), and  $\bar{R}_r$  can be restored to triangular form using two sweeps of plane rotations. Let  $r_q$  be partitioned as  $r_q = (r_1 \ r_2)^T$ , where  $r_1$  is defined as above, and the nonzero entries of the  $(n_s - n_r)$ -vector  $r_2$  are unknown. Applying the plane rotations to  $\bar{R}_r$  requires the two-norm of  $r_2$ . Since  $r_q^T r_q = r_1^T r_1 + r_2^T r_2$ , and  $r_q^T r_q$  is the q-th diagonal of the reduced Hessian  $Z^T H Z$ , the desired norm can be obtained from

$$||r_2||^2 = (Z^T H w)_q - ||r_1||^2.$$

Computing  $||r_2||$  requires forming  $Z^THw$  (instead of  $Z_1^THw$ ). This dominates the work of the BS swap, and requires approximately  $m^2 + mn_s + 2nN$  flops. As before, N is the maximum number of stored limited-memory quasi-Newton updates before a reset. and when a sparse LU factorization of B is used, there is a corresponding reduction in the work.

The update to Z is given by

$$Z = \begin{pmatrix} -\bar{B}^{-1}\bar{S} \\ I \\ 0 \end{pmatrix}, \tag{3.35}$$

where  $\bar{B}$  and  $\bar{S}$  are the result of swapping the p-th column of B with the q-th column of S.

The diagonal matrix D is not updated after the BS Swap, and the "new" q-th superbasic variable is deleted as in Section 3.5.2.

### 3.6 A Quasi-Newton Preconditioner

The second preconditioner is a quasi-Newton approximation of the form

$$R_Q = \left(\begin{array}{cc} T & 0 \\ 0 & D \end{array}\right),$$

where T is a dense  $n_r \times n_r$  upper-triangular matrix and D is a positive diagonal. The matrix T is a quasi-Newton approximation to  $R_r$ , and the elements of D approximate the corresponding diagonal elements of a quasi-Newton approximation to the exact R.

As in Section 3.5 for  $R_C$ , the preconditioner  $R_Q$  will need to be updated for changes in the working set. In addition, a quasi-Newton update for  $R_Q$  must be defined.

### 3.6.1 Updating the Preconditioner

The quasi-Newton update for  $R_Q$  is derived from the BFGS formula. To define a BFGS update for  $R_Q$ , consider the product form of the BFGS update given by (3.15). Let the vectors u and v be given by

$$u = \frac{1}{\|R_Q q\|} q, \qquad v = \frac{1}{\sqrt{y^T q}} y - \frac{1}{\|R_Q q\|} R_Q^T R_Q q,$$

where  $q = \alpha p_z$  and y is the change in  $g_z$ . From (3.15), the standard BFGS update to  $R_Q$  is

$$\bar{R}_Q = R_Q(I + uv^T) = \begin{pmatrix} T & 0 \\ 0 & D \end{pmatrix} (I + uv^T). \tag{3.36}$$

For the BFGS update to  $R_Q$ , only elements of T are updated.

Thus, the new T is given by

$$\bar{T} = T(I + u_r v_r^T), \tag{3.37}$$

where  $u_r$  and  $v_r$  are the first  $n_r$  elements of u and v. After the update to T, two sweeps of plane rotations are used to restore  $\bar{T}$  to upper-triangular form. The work for updating T is  $\mathcal{O}(n_r^2)$  flops.

Let  $R_q$  be a full dense upper-triangular quasi-Newton approximation to the exact R. For the appropriate u and v, the update to  $R_q$  from (3.15) would be

$$\bar{R}_g = R_g + R_g u v^T.$$

Therefore, the update to the diagonals of  $R_q$  given by

$$(\bar{R}_g)_{ii} = (R_g)_{ii} + (R_g u)_i v_i^T$$

depends on the vector  $R_q u$ . For the approximation  $R_Q$ , the (1,2) block is zero, and the (2,2) block is diagonal. Thus, all the information needed for  $R_q u$  is not available. From (3.36), the update to the diagonal elements of D can be defined by

$$(\bar{d})_i = (d)_i [1 + (u)_{n_r+i}(v)_{n_r+i}]$$
 for  $i = 1, \dots, (n_s - n_r)$ . (3.38)

This method is similar to the one used in MINOS for updating a quasi-Newton diagonal extension. However, these are not the diagonals of the quasi-Newton approximation  $R_q$ . For this reason, when  $R_Q$  is used as the preconditioner, the algorithm must include safeguards to ensure that the elements of D remain positive.

The efficiency of any quasi-Newton method depends significantly on the initial  $R_Q$ . When no other information is available, common practice is to initialize  $R_Q$ 

to a multiple of the identity. This convention is used for the first QP subproblem. For subsequent subproblems, the final  $R_Q$  of the previous subproblem is used. This greatly enhances the potential accuracy of the initial estimate, especially for the latter subproblems, when the working set has settled down.

### 3.6.2 The Active Set Strategy

The quasi-Newton approximation  $R_Q$  must be updated to reflect changes to the working set. This requires updates for the three cases defined in Section 2.3.3; adding a superbasic variable, deleting a superbasic variable and deleting a basic variable. Changes to  $R_Q$  for changes in the working set will occur after the quasi-Newton update to  $R_Q$ .

#### Adding a Superbasic Variable

When adding a new superbasic, the new row and column are added to T. Therefore, the quasi-Newton update of (3.37) will be applied to the new column to allow the approximation to incorporate more of the new information. As in Section 3.5.1, one of the superbasics associated with T must be moved to D. The q-th superbasic is chosen by (3.30) and the q-th diagonal of T is moved to D, giving

$$\bar{D} = \begin{pmatrix} D & \\ & t_{qq} \end{pmatrix}.$$

The q-th column of T is deleted and a forward sweep of plane rotations restores T to triangular form. As in Section 3.5.1 for  $R_r$ , after the plane rotations are applied, the last row and column of T are zero. Let  $\hat{T}$  be the  $(n_r - 1) \times (n_r - 1)$  upper-triangular submatrix of T with the zero row and column omitted. A new column for T may be calculated using equations (3.31), with  $\hat{T}$  in place of  $\hat{R}_r$ . This new column will be an approximation to the associated column of  $R_r$ . However, to avoid the work of calculating this column, the new column of T is approximated

by a column of the identity. The update to T is given by

$$\bar{T} = \begin{pmatrix} \hat{T} & 0 \\ 0 & 1 \end{pmatrix},$$

and the update to  $R_Q$  is

$$\bar{R}_Q = \begin{pmatrix} \bar{T} \\ \bar{D} \end{pmatrix}. \tag{3.39}$$

#### Deleting a Superbasic Variable

As in Section 3.5.2, the method of deleting a superbasic variable depends on if the superbasic is associated with T or D. Suppose that the q-th superbasic is to be deleted. If  $q \leq n_r$ , then the q-th column of T is deleted in the same manner as a column is deleted for adding a superbasic. In this case,  $\hat{T}$  is defined as above, i.e., a superbasic associated with D is chosen by (3.33), and the updated T is given by

$$\bar{T} = \begin{pmatrix} \hat{T} & 0 \\ 0 & d_t \end{pmatrix}.$$

The update to D is  $\bar{D} = \text{diag}(d_1, ..., d_{t-n_r-1}, d_{t-n_r+1}, ..., d_{n_s-n_r})$  and  $\bar{R}_Q$  is given by (3.39).

If  $q > n_r$ , then  $\bar{T} = T$  and  $\bar{D} = \text{diag}(d_1, ..., d_{q-n_r-1}, d_{q-n_r+1}, ..., d_{n_s-n_r})$ , and  $\bar{R}_Q$  is given by (3.39).

#### Deleting a Basic Variable

If the p-th basic variable is deleted, the q-th superbasic is chosen to swap into the basis by (2.17). For the quasi-Newton preconditioner, the BS swap update is only performed if  $q \leq n_r$ . The update to T is given by

$$\bar{T} = T - \frac{1}{(y)_q} t_q (y + e_q)^T,$$

where  $(y)_q$  is the q-th element of the vector y such that,  $y = S^T w$  with  $B^T w = e_p$ . The vector  $t_q$  is the q-th column of T. The diagonal extension D is not updated for the BS swap, and two sweeps of plane rotations restore  $\bar{T}$  to triangular form. If  $q > n_r$ , neither T nor D are updated for the BS swap. While  $R_Q$  may not be updated for the BS swap, Z must always be updated according to (3.35).

Again, once the BS swap is performed, the "new" q-th superbasic variable can be deleted.

# 3.7 Using Relaxed Tolerances

The efficiency of the QP method can be improved by appropriate relaxation of RGTOL, the tolerance on the reduced gradient used to indicate convergence on the subspace defined by the current working-set constraints. During the early iterations of each subproblem many of the multipliers will have a non-optimal sign. The work of minimizing accurately on a subspace can be avoided for these early iterations by removing constraints from the working set before a subspace stationary point is reached. When RGTOL is small, constraints are only deleted at subspace stationary points. Thus, the values of  $(\pi, \lambda)$  represent the Lagrange multipliers at those points. If RGTOL is relaxed, then constraints are deleted at non-stationary points. The values of  $(\pi, \lambda)$  at these points are no longer Lagrange multipliers, but are approximations that converge to the multipliers as the iterates approach a subspace stationary point. Relaxing RGTOL exploits the fact that these approximation will often have the correct sign, even though the numerical value is not accurate.

The conjugate-gradient tolerance, CGTOL, is used to terminate the iterates of the CG algorithm. If CGTOL is small, say  $\mathcal{O}(10^{-17})$ , then the reduced-Hessian systems are solved accurately, and the QP search directions generated by the CG method are the same as those generated by SQOPT. During the early iterations when the working set is settling down, a relaxed CGTOL can be used to decrease the work of getting a precise CG solution. The following theorem shows that termination at

any iterate of LSQR will yield a descent direction.

**Theorem 5** Assume that  $H_Z$  is positive definite, and that LSQR is applied to (3.4) with A and b defined by (3.16). Then, if the algorithm is terminated after t iterations, the truncated solution  $d_t$  is a descent direction, in the sense that  $g_Z^T d_t < 0$  for  $0 \le t \le n$ .

**Proof.** The algorithm LSQR is based on the bidiagonalization routine described by BIDIAG. The proof makes use of the description of LSQR presented in Section 3.2. The matrices  $U_{t+1}$ ,  $V_t$  and  $B_t$  are defined by (3.7).

From (3.11), the current iterate is defined as

$$d_t = V_t y_t, (3.40)$$

where  $y_t$  is the solution to the least-squares problem

$$\min \|\beta_1 e_1 - B_t y_t\|.$$

Therefore,  $y_t$  is given by

$$y_t = \beta_1 (B_t^T B_t)^{-1} B_t^T e_1. (3.41)$$

Furthermore, from (3.4) and (3.16) for the reduced-Hessian system, it follows that

$$g_Z = -A^T b. (3.42)$$

Substituting (3.40) and (3.42) into  $g_z^T d_t$  yields

$$g_z^T d_t = -b^T A V_t y_t.$$

By using equations (3.8) and (3.9) this reduces to

$$g_z^T d_t = -\beta_1 e_1^T B_t y_t = -\beta_1 \alpha_1 (e_1^T y_t).$$

Noting that  $B_t^T e_1 = \alpha_1 e_1$ , and substituting from (3.41) yields

$$g_z^T d_t = -\alpha_1^2 \beta_1^2 (e_1^T (B_t^T B_t)^{-1} e_1).$$

By definition,  $U_{t+1}^T U_{t+1} = I$ , and it follows from (3.9) that

$$B_t^T B_t = B_t^T U_{t+1}^T U_{t+1} B_t = V_t^T A^T A V_t.$$

For the definition of A given in (3.16),  $A^TA = H_z$ , thus  $B_t^TB_t = V_t^TH_zV_t$ . Since  $H_z$  is positive definite by assumption, and  $V_t$  is full rank, it follows that  $B_t^TB_t$  is positive definite. Therefore,  $e_1^T(B_t^TB_t)^{-1}e_1 > 0$ , which yields  $g_z^Td_t < 0$ .

This result allows the possibility of using CGTOL to terminate LSQR after only a few LSQR iterations (or possibly none). The initial search direction is the steepest-descent direction,  $-g_z$ . If the system is solved accurately the search direction is equivalent to the SQOPT search direction (up to rounding errors). Thus, the "coarse" descent directions interpolate between these two directions. These coarse directions are often sufficient while the working set is settling down. However, once the working set is optimal, the reduced-Hessian system must be solved accurately to yield the SQOPT direction. Linking the magnitude of CGTOL to the magnitude of the "most" non-optimal multiplier, ensures that the value will be small when the working set is optimal. Let  $\lambda_q$  be the largest magnitude non-optimal multiplier ( $\lambda_q=0$  if all the multipliers have the correct sign). Each time the multipliers are calculated, CGTOL is updated by

$$CGTOL = \max\{\xi | \lambda_q |, CGTOL_0\}, \tag{3.43}$$

where  $\xi$  is a constant parameter such that  $0 < \xi < 1$ . The fixed small tolerance CGTOL<sub>0</sub> must be chosen sufficiently small to ensure that when all the multipliers have optimal sign the algorithm will generate the SQOPT direction.

One possible strategy for implementing the relaxed tolerances would be to use one LSQR iteration, take a step and immediately change the working set if some of the multipliers are non-optimal. This procedure would be repeated until the working set is optimal, at which time the tolerances would be tightened and the problem solved accurately. A flaw of this strategy is that deleting constraints without exact Lagrange multipliers can lead to a bound repeatedly moving in and out of the working set. When the exact Lagrange multipliers are available, and

the t-th constraint is deleted from the working set, the search direction satisfies the relations

$$g^T p < 0$$
 and  $a_t^T p > 0$ ,

where  $a_t^T$  is the normal of the t-th constraint. However, when the exact multipliers are not available, it is possible for  $a_t^T p \leq 0$ . This results in the t-th constraint immediately being added back into the working set. Thus, precautions have to be taken to safeguard against cycling.

An alternative strategy is to not delete a constraint until the reduced gradient has been significantly reduced, in the sense that the norm of  $g_z$  should be less than the magnitude of the "most" non-optimal multiplier,  $\lambda_q$ .

Assume that  $||g_z||$  is less than the current relaxed RGTOL. If some of the multipliers have a non-optimal sign, then a constraint is deleted only if

$$||g_z||_{\infty} \le \theta |\lambda_q|, \tag{3.44}$$

where  $0 < \theta < 1$ . The smaller the value of  $\theta$ , the greater the reduction required in  $g_z$ . When a constraint is successfully deleted, RGTOL is reset for the new subspace to be

$$RGTOL = \max\{\eta \|\bar{g}_z\|_{\infty}, RGTOL_0\},\$$

where  $\eta$  is a constant parameter such that  $0 < \eta < 1$ ,  $\bar{g}_z = (g_z \ \lambda_q)^T$ , and RGTOL<sub>0</sub> is a fixed small tolerance. The smaller the value of  $\eta$  the more accurate the optimization on each subspace. If all the multipliers have their optimal sign, a test is made to see if a solution has been found by checking  $||g_z|| \leq \text{RGTOL}_0$ . If the current point is not a solution, or if (3.44) is not satisfied, then RGTOL is updated by

$$RGTOL = \max\{0.9 ||g_z||_{\infty}, RGTOL_0\}, \tag{3.45}$$

and optimization continues on the current subspace.

While this strategy is admittedly heuristic, a similar approach has been implemented in MINOS with practical success.

# 3.8 Algorithm SQOPT-CG

With the modifications necessary for calculating the search direction and the preconditioner, the algorithm SQOPT-CG can be defined from algorithm SQOPT (see Section 2.3.4). The algorithm is the same as SQOPT except in the definition of the search direction and the choice of tolerances. If  $n_s \leq n_r$  the standard method of SQOPT is used to calculate the search directions. If  $n_s > n_r$  the least-squares CG algorithm LSQR is used. If a small CGTOL is used in LSQR, the search directions of the two algorithms are identical except for rounding error.

The efficiency of Algorithm SQOPT-CG on a given problem is dependent on three modifiable settings.

1. The choice of preconditioner. The work required to calculate and update the preconditioner is significantly greater for the partial reduced-Hessian preconditioner,  $R_C$ , than for the quasi-Newton preconditioner  $R_Q$ . However, the eigenvalue clustering of the preconditioned system should be better with  $R_C$  than with  $R_Q$ . As mentioned, the degree of clustering has a significant impact on the number of CG iterations needed to solve the system. The work needed to maintain a particular preconditioner has to be balanced against the savings in CG iterations.

Obviously, it would be advantageous to avoid the work associated with calculating and updating the preconditioner. For well-conditioned problems, preconditioning is unnecessary and the use of a preconditioner can be avoided.

2. The choice of  $n_r$ . The value of  $n_r$  represents the size of the dense upper-triangular block of the preconditioners  $(R_r \text{ or } T)$ . The larger the value of  $n_r$ , the more beneficial the effect of  $R_r$  and T on the preconditioned system.

Since the direct method is used for  $n_s \leq n_r$ , it would be preferable to use  $n_r \approx 1000$ . However, for problems with  $n_s \gg 1000$ , the work associated with using a matrix  $R_r$  of this size is prohibitive. The work for calculating the initial  $R_r$  is of  $\mathcal{O}(n_r^3)$ , and each solve with  $R_r$  requires  $\mathcal{O}(n_r^2)$  operations. A

more reasonable value of  $n_r$ , say  $200 \le n_r \le 500$ , results in approximately 8-125 times less work in calculating the initial  $R_r$ , and about 4-25 times less work in performing the solves with  $R_r$ .

For the quasi-Newton preconditioner, the work for performing the solves with T remains  $\mathcal{O}(n_r^2)$ . However, the work for calculating the initial  $R_r$  is avoided. This means that larger values of  $n_r$  can exploit the full efficiency of the direct method.

3. The values of η, θ and ξ. Section 3.7 contains a discussion on the benefits of relaxing RGTOL and CGTOL. When RGTOL is relaxed, not minimizing on the subspace saves minor iterations. However, for every constraint deleted in error, the search direction must be recomputed, requiring an additional call to the CG algorithm. The more accurate the optimization on each subspace, the less likely this is to occur. As mentioned is Section 3.7, the accuracy of the optimization on each subspace is controlled by the value of η. A smaller value of η will require more minor iterations, but will result in fewer erroneous modifications to the working set. In addition, constraints are only deleted if (3.44) is satisfied. The smaller the value of θ, the greater the required reduction in the reduced gradient before a constraint can be deleted. A similar scheme implemented in MINOS uses θ = 0.9 and η = 0.2.

A relaxed CGTOL gives a direction that interpolates between the steepest-descent direction and the direction generated by SQOPT. The larger the value of CGTOL, the fewer CG iterations required, and the closer the resulting direction is to the steepest-descent direction. However, the steepest-descent method is notoriously inefficient and a larger than necessary value for CGTOL can yield search directions that are inefficient. The smaller the value of  $|\lambda_q|$ , the more accurately the system is solved. A typical value for  $\xi$  is  $\xi = 0.9$ .

The algorithm SQOPT-CG is now given as follows. The value of  $\theta$ ,  $\eta$  and  $\xi$  are given, and the initial RGTOL and CGTOL are set prior to entering the QP subproblem.

# Algorithm SQOPT-CG Find an initial feasible point, (x, s). Set $n_r$ and choose preconditioner $R_C$ or $R_Q$ Set QN-precon = true or false if $n_s > n_r$ then Initialize the preconditioner: $R_Q = R_Q$ of previous subproblem, or T = I and D = IOR, calculate the initial $R_r^T R_r = Z_r^T H Z_r$ and set D = IelseCalculate the initial $R^T R = Z^T H Z$ end if Calculate the initial g and $\psi$ while true Calculate $g_z$ and $\pi$ $stationary-point = ||g_z|| < \texttt{RGTOL}$ $new-SB = \mathbf{false}$ if stationary-point then Calculate multipliers, $\lambda$ Set $\lambda_q$ to largest magnitude non-optimal multiplier $\mathtt{CGTOL} = \max\{\xi|\lambda_q|,\mathtt{CGTOL}_0\}$ if $\lambda_q = 0$ then if $||g_z|| < \mathtt{RGTOL}_0$ then stop $\mathtt{RGTOL} = \max\{0.9 ||g_z||_{\infty}, \mathtt{RGTOL}_0\}$ else if $||g_z||_{\infty} \le \theta |\lambda_q|$ then Add superbasic corresponding to $\lambda_q$ $\bar{g}_{\scriptscriptstyle Z} = (\begin{array}{cc} g_{\scriptscriptstyle Z} & \lambda_q \end{array})^T$ $new-SB = \mathbf{true}$ $\mathtt{RGTOL} = \max\{\eta \|\bar{g}_Z\|_{\infty}, \mathtt{RGTOL}_0\}$ else $\mathtt{RGTOL} = \max\{0.9 ||g_z||_{\infty}, \mathtt{RGTOL}_0\}$ end if end if

end if

```
if new-SB then
         if n_s > n_r then
              Update the preconditioner
         \mathbf{else}
              Update R
         end if
         Update g_z
   end if
   if n_s > n_r then
         Solve LS problem (3.23) for p_z
    else
         Solve for p_z as in SQOPT
    end if
   Set p = Zp_z
   \alpha_N = maximum feasible step along p
    hit-constraint = \alpha_N < 1
   if hit-constraint then
         \alpha = \alpha_N
    else
         \alpha = 1
   end if
   (x,s) \leftarrow (x,s) + \alpha p
   g \leftarrow g + \alpha H p
   Calculate \psi
   if n_s > n_r and QN-precon then
         Perform BFGS update to R_Q
    end if
   \mathbf{if}\ \mathit{hit\text{-}constraint}\ \mathbf{then}
         if n_s > n_r then
              Update the preconditioner
         else
              Update R
         end if
    end if
end while
```

Typical values for  $CGTOL_0$  and  $RGTOL_0$  are  $10^{-17}$  and  $10^{-6}$  respectively. The same storage space is used for R and the preconditioner  $(R_C \text{ or } R_Q)$ .

### 3.9 Numerical Results

This section gives numerical results for the CG method on a subset of problems from the CUTE test suite [4]. The CUTE test suite is a diverse set of test problems of varying sizes. The CUTE package provides an interface to run the test problems using preset starting points. The problems chosen have a large number of superbasics, with most problems having a maximum value of  $n_s$  that exceeds 1000. Over half of the problems have a value of  $n_s$  of approximately 3000 or more. The largest value of  $n_s$  was 5625. Two problems had a maximum value of  $n_s \approx 600$ .

The test set consists of 74 problems. Of these, 35 are unconstrained problems (UC), 22 are problems with simple bounds only (BO), 10 are nonlinearly constrained problems (NC) and 7 are linearly constrained problems (LC). Table 3.1 lists the problems in the test set, along with the number of variables, n, the maximum value of  $n_s$  attained during the runs, and the problem type.

For all runs, the CG tolerance was set to CGTOL =  $10^{-17}$ . The value of reduced-gradient tolerance was fixed at RGTOL =  $10^{-6}$ . The relaxed tolerance strategy was not used for these runs, therefore, the results compare the methods when generating numerically equivalent search directions. For the SNOPT-CG runs, the value of  $n_r$  was set to 500, and the partial reduced-Hessian preconditioner,  $R_C$ , was used.

The algorithm was implemented in FORTRAN 77 with SNOPT. The runs were made on an SGI R10000 (180MhZ). The performance varied by problem type, thus the results are presented by problem type, with a general summary at the end.

#### 3.9.1 Unconstrained Problems

Table 3.2 gives the run times on the unconstrained problems for SNOPT 5.3 and SNOPT-CG, with and without preconditioning. The times are in seconds. The values of n and  $n_s$  are also included.

The performance of SNOPT-CG on the unconstrained problems is significantly better than SNOPT 5.3. Most of the problems were solved 8-16 times faster using SNOPT-CG with the preconditioner. There were three problems, NCB20, NCB20B and TESTQUAD, where the preconditioned SNOPT-CG runs did not show an improvement, or the performance was worse. In contrast, the SNOPT-CG runs without preconditioning showed improvement for all of the unconstrained problems. The run times for most problems improved by 20-40 times.

Table 3.3, lists the number of major (Maj) iterations, minor (Min) iterations and LSQR iterations for each of the runs. The table shows the number of major and minor iterations for the preconditioned and non-preconditioned runs is the same for most problems. In general, the number of minor iterations for SNOPT-CG was greater than for SNOPT 5.3. The effect of the preconditioner can be examined by comparing the number of LSQR iterations. For most problems, the number of LSQR iterations were approximately the same for both the preconditioned and non-preconditioned runs. In this case, the significant difference in run times reflects the extra work of applying the preconditioner.

The cumulative summary of the results on the unconstrained problems is presented in Table 3.4. The run times are, on average, about 8 times faster using SNOPT-CG with preconditioning, and 20 times faster without preconditioning. Note that the average number of LSQR iterations per minor iterations is very low when compared to the maximum size of  $n_s$  for the test problems.

### 3.9.2 Nonlinearly Constrained Problems

The run times in Table 3.5 indicate the potential of SNOPT-CG on nonlinearly constrained problems. In general, performance was 3-5 times faster, and

in the case of DTOC6 and SINROSNB, over 50 times faster. The improvement is most significant for problems where many iterations are required with a large number of degrees of freedom. The combined effect of not computing the full R, and only computing new columns of dimension  $n_r$  (vs.  $n_s$ ) is magnified for the nonlinear problems. This benefit is even reflected in the smaller problems LCH and READING9, where  $n_s$  is only 600, but the run continues for 1000 iterations.

The preconditioner has the greatest success in reducing the number of LSQR iterations on the nonlinearly constrained problems. In Table 3.6, most problems show a reduction in the number of LSQR iterations with the preconditioner. The average reduction for these problems was 23%. In addition, without preconditioning the problem SINROSNB terminates at a search direction that is not a descent direction. However, the execution times for the runs without preconditioning are still better than those with preconditioning. Thus, the benefit of the preconditioner is not sufficient to overcome its inherent additional cost.

The number of minor iterations for SNOPT-CG is higher than for SNOPT 5.3. However, the use of the preconditioner required fewer minor iterations than the runs without preconditioning.

Table 3.7 summarizes the totals for the nonlinearly constrained problems. The

results for SINROSNB are not included. The numbers are dominated by the results for DTOC6. The average number of LSQR iterations per minor iteration is again very small.

## 3.9.3 Linearly Constrained Problems

In contrast to the unconstrained and nonlinearly constrained problems, where SNOPT-CG exhibits a significant improvement, the performance on linearly constrained problems is generally poorer than for SNOPT 5.3. Table 3.8 gives the run times for SNOPT-CG on the linearly constrained problems. As mentioned in Section 2.2, SNOPT 5.3 is more efficient on problems where all the constraints are linear. This is a result of R not needing to be refactorized after each major iteration. The performance of SNOPT-CG on the problems where  $n_s \approx 1000$  is worse than SNOPT 5.3. However, on problems where  $n_s > 2000$ , SNOPT-CG starts to show modest improvement, with the best results being for the problem with the largest maximum value of  $n_s$ .

Table 3.9 shows the number of major and minor iterations is essentially the same for all the runs. In general, the number of LSQR iterations is significantly higher for the preconditioned runs. A notable exception was MOSARQP1, where the preconditioner reduced the number of LSQR iterations by almost 80%. However, despite the significant reduction in the LSQR iterations, there was only a modest improvement in the run time.

The cumulative totals for the linearly constrained problems are given in Table 3.10. The average number of LSQR iterations per minor iteration is larger than for the unconstrained and nonlinearly constrained problems. However, the values are still small relative to the size of  $n_s$ .

#### 3.9.4 Problems with Only Simple Bounds

The results for problems with only simple bounds are mixed. In general, performance depends on the number of active bounds. Times on problems where  $n - n_s$  stays small (say  $\leq 1200$ ) more closely resemble those for an unconstrained problem. In contrast, when  $n - n_s$  is large, which implies that many bounds are active, the run-times resemble those for the simple linearly constrained problems, and the performance on these problems is more modest.

A notable exception to this trend are the TORSION problems. When preconditioning was used, the performance on these problems was generally worse than that of SNOPT 5.3. Without preconditioning, SNOPT-CG showed only a modest improvement

Comparing the LSQR iterations in Table 3.12 shows that the preconditioner performed very poorly on problems with only simple bounds.

The cumulative totals for the problems with only simple bounds are given in Table 3.13. The average number of LSQR iterations per minor iteration is similar to the numbers for the linearly constrained problems.

## 3.9.5 Summary

The overall performance of the CG method is typical of that of other iterative methods, in the sense that performance is extremely problem dependent. In general, the method performed well on unconstrained problems, nonlinearly constrained problems, and problems with simple bounds with relatively few active bounds (i.e.,  $n_s \approx n$ ).

The preconditioner performed best on problems with nonlinear constraints. However, the improvement in iterations tended to be overwhelmed by the cost of applying the preconditioner. Performance was best for SNOPT-CG without preconditioning. This may be caused by the low average number of LSQR iterations per minor iteration. The overall average for the runs without preconditioning was 14.7 LSQR iterations per minor iteration. This value is small relative to the typical

size of  $n_s$ , thus it may have been difficult for the preconditioner to significantly reduce the number of LSQR iterations. However, there is evidence that preconditioning is necessary for some problems. The quasi-Newton preconditioner avoids much of the work associated with preconditioning and will likely provide a better alternative to the partial reduced-Hessian preconditioner.

# Chapter 4

# The Schur-Complement Method

The Schur-complement QP algorithm of Gill et al. [20], maintains a fixed factorization of the initial KKT system, and updates a smaller dense factorization of a Schur complement. These factorizations are used to compute the search directions and multipliers for the quadratic program. The method proposed in this chapter uses a Schur complement-based algorithm to solve the QP subproblems.

The method uses an extended KKT system associated with a specially defined working set (see below). This modification improves the efficiency of existing methods by defining simpler linear systems at each iteration. In addition, the efficiency is improved by limiting the number of updates to the dense Schur complement.

In the final section of this chapter, a new Schur-complement method is derived based on minimizing an  $\ell_2$  composite objective function. This single phase algorithm does not require the two-phase approach of SQOPT for finding a feasible point.

Sections 4.1 and 4.2 review the theory and development of a general algorithm for convex quadratic programming used for the Schur-complement method. The proposed Schur-complement method is presented in Sections 4.3–4.4. Finally, Section 4.5 discusses the use of a composite objective function, with an  $\ell_2$  penalty term, when the initial point is not feasible.

# 4.1 Convex Quadratic Programming

Consider a QP of the form:

minimize 
$$f(x) \equiv c^T x + \frac{1}{2} x^T H x$$
  
subject to  $Ax \ge b$ .

Assume that H is positive semidefinite and  $x_0$  is feasible. Define the constraint residual r(x) = Ax - b and objective gradient g(x) = c + Hx.

Active-set quadratic programming (QP) methods use a working set of the constraint gradients to define the search direction and multiplier estimates. In the methods proposed here, the working set is chosen to control the inertia of the reduced Hessian, which is never permitted to have more than one zero eigenvalue. Such methods are called *inertia-controlling*.

Given a matrix W of full row rank, a point x such that  $g(x) = W^T \lambda$  for some vector  $\lambda$  is known as a subspace stationary point (with respect to W). Given a null-space basis Z for W, a subspace stationary point such that  $Z^T H Z$  is positive definite is known as a subspace minimizer (with respect to W). A feasible point is optimal if the vector  $\lambda$  is nonnegative at a subspace minimizer.

At a point  $x_k$ , the matrix W will be defined as a linearly independent subset  $W_k$  of the rows of A determined by an index set  $W_k$  known as a working set. Assume for the moment that  $x_k$  and  $W_k$  are defined such that every constraint in  $W_k$  is active, i.e.,  $W_k = \{i \mid a_i^T x_k = \beta_k\}$ . Moreover, assume that  $x_k$  is a non-optimal subspace minimizer with respect to  $W_k$ , in which case there exists an index t in  $W_k$  such that

$$g_k = W_k^T \lambda_k, \quad \text{and} \quad (\lambda_k)_t < 0.$$
 (4.1)

At this point it is useful to partition  $W_k$  so that the constraint  $a_t^T x \geq \beta_t$  is separate from the other constraints in the working set. In particular, it is assumed for notational purposes that the working-set matrix can be arranged in the form

$$W_k = \begin{pmatrix} A_k \\ a_t^T \end{pmatrix}, \tag{4.2}$$

where  $A_k$  is the matrix with rows  $\{a_i^T\}$  for  $i \in \mathcal{W}_k$ ,  $i \neq t$ .

As  $(\lambda_k)_t$  is negative, Farkas' Lemma implies that there must exist a direction p that reduces f while satisfying the feasibility conditions

$$A_k p = 0$$
 and  $a_t^T p > 0$ .

These conditions ensure that the constraints with gradients in  $A_k$  will remain active at any step of the form  $x_k + \alpha p_k$ . (This motivates the use of the notation "A" for "active" working-set constraints.) An obvious choice for p is the vector that both satisfies these conditions and minimizes  $f(x_k + p)$ . This vector, denoted by  $p_k$ , is defined by the equality-constraint subproblem

$$\underset{p \in \mathbb{R}^n}{\text{minimize}} \ g_k^T p + \frac{1}{2} p^T H p, \qquad \text{subject to } A_k p = 0,$$

and satisfies the system

$$\begin{pmatrix} H & A_k^T \\ A_k & 0 \end{pmatrix} \begin{pmatrix} p_k \\ -\pi_k \end{pmatrix} = \begin{pmatrix} -g_k \\ 0 \end{pmatrix}, \tag{4.3}$$

where the vector  $\pi_k$  is the vector of multipliers at the subspace stationary point  $x_k + p_k$  (which may or may not be feasible with respect to constraints not in the working set). Once  $p_k$  is defined, the step  $\alpha_k$  is required to retain feasibility with respect to constraints not in the working set. If  $\alpha_B$  denotes the step to the blocking constraint, the step  $\alpha_k$  is given by  $\alpha_k = \min\{1, \alpha_B\}$ . If  $\alpha_B \geq 1$ , then  $x_k + p_k$  is feasible, and  $x_k + p_k$  is a subspace stationary point with respect to  $A_k$ . Otherwise,  $\alpha_k = \alpha_B < 1$  and the working set is modified to include the blocking constraint that is satisfied exactly at the new point. (If  $\alpha_B$  is the maximum feasible step for more than one constraint, so that there is a "tie" in the nearest constraint, an active-set method typically adds only one constraint to the working set at each iteration.)

In the strictly convex case, H is positive definite and the system (4.3) for  $p_k$  is nonsingular. However, in the general convex case, the reduced Hessian  $Z_k^T H Z_k$  (and hence also the system (4.3)) may be singular. The strategy used here is

to choose the working set to control the inertia of the reduced Hessian, which is never permitted to have more than one zero eigenvalue. Such methods are called inertia-controlling. At any initial iterate  $x_0$ , it is always possible to find enough real or temporary constraints to define a working set  $W_0$  with a nonsingular  $Z_0^T H Z_0$ . Thereafter, it can be shown that the reduced Hessian can become singular only when a constraint is deleted from the working set. When  $Z_k^T H Z_k$  is singular at a non-optimal point, it is used to define a direction  $p_z$  such that

$$Z_k^T H Z_k p_z = 0 \quad \text{and} \quad g_k^T Z_k p_z < 0.$$

The vector  $p_k = Z_k p_z$  is a direction of unbounded descent in the sense that the objective is linear in that direction and decreases without bound along  $p_k$ . Normally, a step along  $p_k$  reaches a new constraint, which is then added to the working set for the next iteration. (If no constraint can be added to the working set, the problem must be unbounded and the algorithm terminates.) In an inertia-controlling strategy, no further constraints are deleted until the reduced Hessian becomes nonsingular.

The calculation of a direction of unbounded descent is relatively straightforward if  $Z_k^T H Z_k$  is computed explicitly. In this case,  $p_k$  can be computed from a triangular system involving the (singular) Cholesky factor of  $Z_k^T H Z_k$  (see, e.g., [21]). If the reduced Hessian cannot be computed (because of sparsity considerations for example) a vector  $p_k$  can be computed from a nonsingular system with matrix

$$K = \begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix}, \tag{4.4}$$

where  $W_k$  includes the gradient  $a_t$  of the most recently deleted constraint. The theory of this type of method is based on the next result, given, e.g., by [21].

**Lemma 3** Let  $W_k$  be an  $m \times n$  matrix of full row rank, and let A denote W with its t-th row omitted, so that  $A_k$  also has full row rank. The matrices Z and  $Z_W$  denote null-space bases for  $A_k$  and  $W_k$ , and  $Z_k^T H Z_k$  and  $Z_W^T H Z_W$  denote the associated

reduced Hessian matrices. Define K and  $K_W$  as

$$K = \left(egin{array}{cc} H & A_k^T \ A_k & 0 \end{array}
ight) \quad and \quad K_W = \left(egin{array}{cc} H & W_k^T \ W_k & 0 \end{array}
ight),$$

where H is an  $n \times n$  symmetric matrix. Consider the nonsingular linear system

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} u_k \\ \mu_k \end{pmatrix} = K_W \begin{pmatrix} u_k \\ \mu_k \end{pmatrix} = \begin{pmatrix} 0 \\ e_t \end{pmatrix}, \tag{4.5}$$

where  $u_k$  has n components. Let  $(\mu_k)_t$  denote the t-th component of  $\mu_k$ . If  $Z_W^T H Z_W$  is positive definite, then if  $(\mu_k)_t < 0$  then  $Z_k^T H Z_k$  is positive definite; if  $(\mu_k)_t = 0$  then  $Z_k^T H Z_k$  is singular.

In the singular case,  $(\mu_k)_t = 0$ , and the first n equations of (4.5) imply that

$$0 = u_k^T H u_k + u_k^T A_k^T \mu_E = u_k^T H u_k.$$

It follows that the direction  $p_k = u_k$  satisfies both the descent condition  $p_k^T H p_k = 0$  and  $g_k^T p_k < 0$ , as well as the feasibility conditions  $A_k p_k = 0$  and  $a_t^T p_k > 0$ .

It remains to be shown how the direction  $p_k$  of (4.3) may be computed from a system with matrix (4.4). The following result shows how this can be done.

**Lemma 4** Let  $x_k$  be a non-optimal subspace minimizer with respect to  $W_k$ . Let t be the index of a column of  $W_k$  such that  $g_k = W_k^T \lambda_k$  and  $(\lambda_k)_t < 0$ . Let  $u_k$  denote the solution of the system

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} u_k \\ -\nu_k \end{pmatrix} = \begin{pmatrix} -g_k \\ e_t \end{pmatrix}. \tag{4.6}$$

If  $p_k$  is the direction  $p_k = \sigma_k u_k$ , with  $\sigma_k = (\lambda_k)_t/(\mu_k)_t$ , then  $x_k + p_k$  minimizes f on the manifold  $\{x \mid A_k x = b_k\}$ .

**Proof.** The vector  $p_k$  defined by the system (4.3) minimizes f on the manifold  $\{x \mid a_i^T x = \beta_i, i \in \mathcal{W}_k, i \neq t\}$ . Let  $\bar{\pi}_k$  denote the  $m_k$ -vector obtained from  $\pi_k$  by inserting a zero component in the t-th position, i.e.,

$$(\bar{\pi}_k)_i = \begin{cases} (\pi_k)_i & \text{if } i < t; \\ 0 & \text{if } i = t; \\ (\pi_k)_{i-1} & \text{if } i > t. \end{cases}$$

Then

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} p_k \\ -\bar{\pi}_k \end{pmatrix} = \begin{pmatrix} -g_k \\ \sigma e_t \end{pmatrix}, \tag{4.7}$$

where  $\sigma = a_t^T p_k$  and  $a_t$  is the t-th row of  $W_k$ .

Since  $x_k$  is a subspace minimizer with respect to  $W_k$ , the optimality conditions  $g_k = W_k^T \lambda_k$  must hold, and the multipliers  $\lambda_k$  may be interpreted as satisfying the expanded system

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} 0 \\ -\lambda_k \end{pmatrix} = \begin{pmatrix} -g_k \\ 0 \end{pmatrix}. \tag{4.8}$$

Subtracting this equation from (4.7) yields

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} p_k \\ \lambda_k - \bar{\pi}_k \end{pmatrix} = \begin{pmatrix} 0 \\ \sigma e_t \end{pmatrix}.$$

Similarly, subtracting (4.8) from (4.6) gives

$$\begin{pmatrix} H & W_k^T \\ W_k & 0 \end{pmatrix} \begin{pmatrix} u_k \\ \mu_k \end{pmatrix} = \begin{pmatrix} 0 \\ e_t \end{pmatrix}, \quad \text{with } \mu_k = \lambda_k - \nu_k. \tag{4.9}$$

(cf. (4.5) These identities imply that  $p_k = \sigma u_k$  and  $x_k + p_k = x_k + \sigma u_k$ .

It remains to find a form of  $\sigma$  that is independent of  $p_k$ . From the definition of  $p_k$ , the point  $\alpha = 1$  minimizes  $f(x_k + \alpha p_k)$  as a function of  $\alpha$ . If  $\sigma_k$  minimizes  $f(x_k + \alpha u_k)$ , the collinearity of  $p_k$  and  $u_k$  implies that  $x_k + p_k$  and  $x_k + \sigma_k u_k$  are

the same point. The univariate minimizer  $\sigma_k$  may be computed using the identity

$$\left. \frac{d}{d\alpha} f(x_k + \alpha u_k) \right|_{\alpha = \sigma_k} = g_k^T u_k + \sigma_k u_k^T H u_k = 0,$$

which implies  $\sigma_k = -g_k^T u_k / u_k^T H u_k$ . The required form of  $\sigma_k$  now follows from (4.9) and (4.1) using the relations  $-u_k^T H u_k = u_k^T W_k^T \mu_k = e_t^T \mu_k = (\mu_k)_t$ , and  $g_k^T u_k = \lambda_k^T W_k u_k = \lambda_k^T e_t = (\lambda_k)_t$ .

Once  $p_k$  is defined, the step  $\alpha_k$  is required to retain feasibility with respect to constraints not in the working set. If  $\alpha_B$  denotes the step to the blocking constraint, the step  $\alpha_k$  is given by  $\alpha_k = \min\{1, \alpha_B\}$ . If  $\alpha_B \geq 1$ , then  $x_k + p_k$  is feasible, and  $x_k + p_k$  is a subspace stationary point with respect to  $A_k$ . Otherwise, if  $\alpha_B < 1$ , then  $\alpha_k = \alpha_B$  and the working set is modified to include the blocking constraint that is satisfied exactly at the new point. (If  $\alpha_B$  is the maximum feasible step for more than one constraint, so that there is a "tie" in the nearest constraint, an active-set method typically adds only one constraint to the working set at each iteration.)

The intent is to be able to use a system of the form (4.6) to define the search direction at every iteration. However, the properties of the linear system (4.6) of Lemma 4 depend upon  $x_k$  being a subspace minimizer with respect to  $W_k$ . This is certainly the case if the step  $x_{k+1} = x_k + p_k$  is taken, since  $x_{k+1}$  is then a subspace minimizer with respect to the constraints in  $A_k$ . (In this case the new working set  $W_{k+1}$  is just  $A_k$ , which is  $W_k$  with row  $a_t^T$  deleted.)

Unfortunately, stationarity with respect to  $A_k$  does not usually hold when  $\alpha_k < 1$  (i.e., when progress along  $p_k$  is impeded by a blocking constraint). This difficulty is treated by redefining what is meant by a "working set". In particular, the most recently deleted constraint  $a_t^T x \geq \beta_t$  may be retained in the working set even though the constraint may be inactive at the current point. Suppose that  $p_k$  is computed as in Lemma 4, and a new constraint  $a_r^T x \geq \beta_r$  is added to the working

set at  $x_{k+1} = x_k + \alpha_k p_k$ . Define the new working-set matrix as

$$W_{k+1} = \begin{pmatrix} A_{k+1} \\ a_t^T \end{pmatrix}, \text{ where } A_{k+1} = \begin{pmatrix} A_k \\ a_r^T \end{pmatrix}.$$

Consider a non-optimal subspace minimizer  $x_k$  at which all the working-set constraints are active. If  $W_k$  is partitioned in terms of  $A_k$  and the constraint to be deleted (see (4.2)), it follows that

$$g_k = A_k^T \lambda_E^k + \lambda_t^k a_t, \quad \text{with} \quad \lambda_t^k < 0, \tag{4.10}$$

where  $\lambda_E^k$  denotes the multiplier vector corresponding to  $A_k$  and  $\lambda_t^k$  denotes the (necessarily negative) multiplier  $(\lambda_k)_t$ .

The next result shows that  $x_{k+1}$  is itself a subspace minimizer with respect to a particular set of *shifted* constraints with working-set matrix  $W_{k+1}$ .

**Lemma 5** Let  $g_k$  and  $W_k$  denote the gradient and working set at a non-optimal subspace minimizer  $x_k$ . Assume that  $W_k$  is partitioned as in (4.2), with  $a_t$  defined so that

$$g_k = A_k^T \lambda_E^k + \lambda_t^k a_t, \quad with \quad \lambda_t^k < 0, \tag{4.11}$$

for some vector  $\lambda_E^k$  and scalar  $\lambda_t^k$ . Let  $x_{k+1} = x_k + \alpha_k p_k$ , and assume that constraint  $a_r$  is added to  $W_k$  at  $x_{k+1}$  to give the working set  $W_{k+1}$ . Then

- (a)  $g_{k+1}$ , the gradient at  $x_{k+1}$ , is also a linear combination of  $A_k^T$  and  $a_t$ ;
- (b) There exist a vector  $\lambda_{\scriptscriptstyle E}^{k+1}$  and scalar  $\lambda_t^{k+1}$  such that

$$g_{k+1} = A_{k+1}^T \lambda_E^{k+1} + \lambda_t^{k+1} a_t, \quad with \quad \lambda_t^{k+1} < 0.$$
 (4.12)

**Proof.** Because f is quadratic, the gradients at  $x_k$  and  $x_{k+1}$  are related by the identity

$$g_{k+1} = g(x_k + \alpha_k p_k) = g_k + \alpha_k H p_k.$$
 (4.13)

The form of  $g_{k+1}$  for the two definitions of  $p_k$  is now considered.

When the reduced Hessian is positive definite, p satisfies (4.3), and it follows that  $Hp_k = -g_k + A_k^T \pi_k$ . Substituting from this expression and (4.10) in (4.13), yields

$$g_{k+1} = g_k + \alpha_k H p_k = (1 - \alpha_k) g_k + \alpha_k A_k^T \pi_k = A_k^T \nu_E + \lambda_t^{k+1} a_t,$$

where  $\nu_E = (1 - \alpha_k)\lambda_k + \alpha_k \pi_k$  and  $\lambda_t^{k+1} = (1 - \alpha_k)\lambda_t^k$ . Because a constraint was added to the working set at  $x_{k+1}$ , it must hold that  $\alpha_k < 1$  and hence  $\lambda_t^{k+1} < 0$ . The expression (b) is obtained by forming  $\lambda_{k+1}$  from  $\nu_E$  and a zero component corresponding to row  $a_r^T$  in  $A_{k+1}$ .

When the reduced Hessian is singular,  $p_k$  is defined as  $u_k$ , where  $u_k$  satisfies (4.9), so that  $Hp_k = -A_k^T \mu_E$ . Substituting from this relation and (4.10) in (4.13) gives

$$g_{k+1} = g_k + \alpha_k H p_k = g_k - \alpha_k A_k^T \mu_E = A_k^T (\lambda_E^k - \alpha_k \mu_E) + \lambda_t^k a_t,$$

and (4.12) holds with  $\lambda_t^{k+1} = \lambda_t^k$  and  $\lambda_E^{k+1}$  formed by augmenting  $\nu_E = \lambda_E^k - \alpha_k \mu_E$  with a zero component as above.

This lemma implies that  $x_{k+1}$  can be regarded as the solution of a problem in which the most recently deleted constraint is *shifted* to pass through the point  $x_{k+1}$ ; i.e.,  $x_{k+1}$  solves the equality-constraint problem

minimize 
$$c^T x + \frac{1}{2} x^T H x$$
  
subject to  $A_k x = b_k$ ,  $a_t^T x = a_t^T x_{k+1}$ .

Note that this problem can be solved without needing to know  $x_{k+1}$  in advance. The optimal multipliers are the quantities  $(\lambda_E^{k+1}, \lambda_t^{k+1})$  of Lemma 5. More specifically, the scalar  $\lambda_t^k$  is the multiplier corresponding to the shifted constraint  $a_t^T x \geq a_t^T x_{k+1}$ .

If the step  $\alpha_k = 1$  is taken to reach the point  $x_{k+1}$ , this multiplier becomes zero, which implies that  $x_{k+1}$  is a subspace minimizer with respect to both  $A_k$  and  $W_k$ .

A simple inductive argument shows that in a sequence of consecutive steps at which a constraint is added to the working set, each iterate is a subspace minimizer of an appropriately shifted problem. To simplify the notation, consider an initial feasible point  $x_0$ , and an initial working set  $A_0$  such that  $x_0$  is not a minimizer with respect to  $A_0$ . It follows from the above discussion that a sequence of N+1  $(N \geq 0)$  consecutive iterates is defined such that  $x_{N+1}$  is the first minimizer—i.e.,  $x_{N+1}$  is a minimizer with respect to  $A_{N+1}$ , but none of the  $x_k$  is a minimizer with respect to  $A_k$  for  $0 \leq k \leq N$ . At each of the first N steps,  $\alpha_k < 1$  and a constraint is added to the working set. At the Nth iteration one of two things can happen. If  $A_{N+1} = A_N$  and an "unconstrained" step  $\alpha_N = 1$  is taken, the sequence of iterates may be represented schematically as

Alternatively,  $x_{N+1}$  can be a minimizer after a constrained step  $\alpha_N < 1$ . This will happen, for example, if  $x_{N+1}$  is a vertex, since a vertex is trivially a subspace minimizer with respect to  $A_k$ . In this case,

The structure above suggests the name of *intermediate* iterates for the points  $\{x_k\}$ , k = 0, 1, ..., N. Essentially, a point  $x_k$  is an intermediate iterate if it is not a subspace stationary point with respect to  $A_k$ .

If a constraint is now deleted at  $x_{N+1}$ , a new sequence of intermediate iterates is started, beginning with the point  $x_{N+1}$  (suitably relabeled to reflect the fact that a constraint has been deleted from  $A_{N+1}$ ). Note that for any sequence of consecutive intermediate iterates, N can be zero (when the first step locates a minimizer), but no greater than n (the number of steps from an unconstrained point to a vertex minimizer).

The properties of a group of consecutive intermediate iterates that occur after a constraint is deleted at a subspace minimizer, but before the next minimizer is reached, are now examined. Each such iterate is associated with a unique most recently deleted constraint. Consider a sequence of consecutive intermediate iterates

 $\{x_k\}, k = 0, \ldots, N$ , such that  $x_k$  is intermediate with respect to  $A_k$ . Assume that the first working set has the form

$$W_0 = \begin{pmatrix} A_0 \\ a_t^T \end{pmatrix}, \tag{4.14}$$

and that  $x_0$  is a subspace minimizer with respect to  $W_0$ .

Let  $Z_W$  denote a basis for the null space of W. Because of the inertia-controlling strategy, the reduced Hessian  $Z_W^T H Z_W$  must be positive definite. Relation (4.14) implies that

$$p^T H p > 0$$
 for any nonzero  $p$  such that  $A_0 p = 0$  and  $a_t^T p = 0$ . (4.15)

If the iterate following  $x_k$  is intermediate and the algorithm continues,  $\alpha_k$  is the step to the nearest constraint, and a constraint is added to the working set at each  $x_k$ ,  $k \geq 1$ . If a constraint is added, it must hold that  $\alpha_k < 1$ . (Otherwise, if  $\alpha_k = 1$ ,  $x_k + p_k$  is a subspace minimizer with respect to  $A_k$ , and the sequence of intermediate iterates ends.) Let  $a_k$  denote the normal of the constraint added to  $A_k$  at  $x_{k+1}$  to produce  $A_{k+1}$ , so that the form of  $W_{k+1}$  and  $A_{k+1}$  is

$$W_{k+1} = \begin{pmatrix} A_{k+1} \\ a_t^T \end{pmatrix}, \quad \text{and} \quad A_{k+1} = \begin{pmatrix} A_k \\ a_k^T \end{pmatrix} = \begin{pmatrix} A_0 \\ a_0^T \\ \vdots \\ a_k^T \end{pmatrix}. \tag{4.16}$$

Some useful results are now derived concerning the sequence of intermediate iterates.

**Lemma 6** Given a sequence of consecutive intermediate iterates  $\{x_k\}$ , the gradient  $g_k$  satisfies (4.11) for  $k \geq 0$ .

**Proof.** To begin the induction, note that if the multiplier associated with  $a_t$  at  $x_0$  is negative, then, from (4.14),

$$g_0 = A_0^T \lambda_E^0 + \lambda_t^0 a_t,$$

where  $\lambda_t^0 < 0$ . Lemma 5 therefore applies at all subsequent intermediate iterates, with the convention that  $\lambda$  increases in dimension by one at each step to reflect the fact that  $A_k$  has one more row than  $A_{k-1}$ .

**Lemma 7** Let  $\{x_k\}$  be a sequence of consecutive intermediate iterates. Each search direction satisfies  $g_k^T p_k < 0$  and  $a_t^T p_k > 0$ .

**Proof.** From part (b) of Lemma 6, for the stated values of k, there exist a vector  $\lambda_E^k$  and positive scalar  $\lambda_t^k$  such that

$$g_k = A_k^T \lambda_E^k + \lambda_t^k a_t.$$

Therefore,  $g_k^T p_k = \lambda_t^k a_t^T p_k$  and the desired results are immediate.

**Lemma 8** Let  $\{x_k\}$ , k = 0,..., N, denote a sequence of consecutive intermediate iterates. Assume further that  $\alpha_N$  is the step to the constraint with normal  $a_N$ , which is added to  $A_N$  to form the working set  $A_{N+1}$ . Let  $x_{N+1} = x_N + \alpha_N p_N$ . Then

- (a) If  $x_{N+1}$  is a stationary point with respect to  $A_{N+1}$ , then  $a_N$  is linearly dependent on  $A_N^T$  and  $a_t$ , and  $Z_{N+1}^T H Z_{N+1}$  is positive definite;
- (b) If  $a_N$  is linearly dependent on  $A_N^T$  and  $a_t$ , then  $x_{N+1}$  is a minimizer with respect to  $A_{N+1}$ .

**Proof.** By construction, the working set (4.14) has full row rank, so that  $a_t$  is linearly independent of the rows of  $A_0$ . From part (b) of Lemma 6

$$g_k = A_k^T \lambda_E^k + \lambda_t^k a_t, \qquad k = 0, \dots, N, \tag{4.17}$$

where  $\lambda_t^k < 0$ . Since it is assumed that  $x_k$  is not a subspace stationary point with respect to  $A_k$  for any  $1 \le k \le N$ , (4.17) shows that  $a_t^T$  is linearly independent of  $A_k$ . Furthermore, part (a) of Lemma 5 implies that there exists a vector  $\nu_E$  such that

$$g_{N+1} = A_N^T \nu_E + \lambda_t^{N+1} a_t, (4.18)$$

where  $\lambda_t^{N+1} < 0$ . It follows from the linear independence of  $a_t^T$  and  $A_N$  that  $x_{N+1}$  cannot be a minimizer with respect to  $A_N$ .

To show part (a), assume that  $x_{N+1}$  is a stationary point with respect to  $A_{N+1}$  (which includes  $a_N$ ), i.e.,

$$g_{N+1} = A_N^T \pi + \pi_N a_N, (4.19)$$

where  $\pi_N$  (the multiplier associated with  $a_N$ ) must be nonzero. Equating the right-hand sides of (4.18) and (4.19), yields

$$A_N^T \nu + \lambda_t^{N+1} a_t = A_N^T \pi + \pi_N a_N. \tag{4.20}$$

Since  $\lambda_t^{N+1} \neq 0$  and  $\pi_N \neq 0$ , this expression implies that  $a_t$  may be expressed as a linear combination of  $A_N^T$  and  $a_N$ , where the coefficient of  $a_N$  is nonzero:

$$a_t = A_N^T \xi + \gamma a_N$$
, with  $\gamma = \frac{\pi_N}{\lambda_t^{N+1}} \neq 0$  (4.21)

and  $\xi = (1/\lambda_t^{N+1})(\pi - \nu)$ .

Stationarity of  $x_{N+1}$  with respect to  $A_{N+1}$  thus implies a special relationship among the most recently deleted constraint, the working set at  $x_N$  and the newly encountered constraint. Any nonzero vector p in the null space of  $A_{N+1}$  satisfies

$$A_{N+1}p = \begin{pmatrix} A_N \\ a_N^T \end{pmatrix} p = 0. \tag{4.22}$$

For any such p, it follows from the structure of  $A_{N+1}$  (see (4.16)) that  $A_0p = 0$ , and from (4.21) that  $a_t^T p = 0$ ; hence, p lies in the null space of W. Since  $Z_w^T H Z_w$  is positive definite (i.e., (4.15) holds), it follows that  $p^T H p > 0$  for p satisfying (4.22). Thus, the reduced Hessian at  $x_{N+1}$  with respect to  $A_{N+1}$  is positive definite, and  $x_{N+1}$  is a minimizer with respect to  $A_{N+1}$ .

To verify part (b), assume that  $a_N$  is linearly dependent on  $A_N$  and  $a_t$ , i.e., that  $a_N = A_N^T \beta + a_t \beta_t$ , where  $\beta_t \neq 0$ . Simple rearrangement then gives  $a_t = (1/\beta_t)a_N - (1/\beta_t)A_N^T \beta$ . Substituting in (4.18), yields

$$g_{N+1} = A_N^T \nu + \frac{\lambda_t^{N+1}}{\beta_t} a_N + \frac{\lambda_t^{N+1}}{\beta_t} A_N^T \beta,$$

which shows that  $x_{N+1}$  must be a subspace stationary point with respect to  $A_{N+1}$ . Positive definiteness of the reduced Hessian follows as before, and hence  $x_{N+1}$  is a minimizer with respect to  $A_{N+1}$ .

Lemma 8 is crucial in ensuring that *adding* a constraint in an inertia-controlling algorithm cannot produce a stationary point where the reduced Hessian is not positive definite.

## 4.2 Implementation

In addition to the search direction and work vectors, the proposed algorithm requires the storage of the five vectors: u,  $\mu$ , z,  $\eta$ , and  $\lambda$ , where  $\lambda$  is the multiplier vector satisfying  $W^T\lambda = g$ . These vectors are needed to solve the following systems:

System 0 (initialization) 
$$\begin{pmatrix} H & W_0^T \\ W_0 & 0 \end{pmatrix} \begin{pmatrix} p_0 \\ -\lambda_0 \end{pmatrix} = -\begin{pmatrix} g_0 \\ r_0 \end{pmatrix}, (4.23)$$

System 1 (constraint deletion) 
$$\begin{pmatrix} H & W^T \\ W & 0 \end{pmatrix} \begin{pmatrix} u \\ \mu \end{pmatrix} = \begin{pmatrix} 0 \\ e_t \end{pmatrix}, \quad (4.24)$$

System 2 (constraint addition) 
$$\begin{pmatrix} H & W^T \\ W & 0 \end{pmatrix} \begin{pmatrix} z \\ \eta \end{pmatrix} = \begin{pmatrix} a_r \\ 0 \end{pmatrix}.$$
 (4.25)

System 0 is solved only once, for the initial values of x and  $\lambda$ . At a subspace minimizer, System 1 is solved for u and  $\mu$ . The search direction p is defined to be either  $\sigma u$  or u depending on whether or not the reduced Hessian is singular after  $a_t$  is deleted from the working set. (This information is provided by the sign of  $(\mu)_t$ ). Once the step  $\alpha$  has been determined, the multipliers  $\lambda$  are updated to reflect the change in g resulting from the move from x to  $x + \alpha p$ . (The specific updates require the current values of the vectors u and  $\mu$ .) If a constraint is added to the working set, the vectors u,  $\mu$  and  $\lambda$  must be updated to reflect the addition

of the new row to W. These vectors are updated using the quantities z and  $\eta$  calculated from System 2. Each time a constraint is added, u and  $\mu$  are updated, requiring an additional solve with System 2.

This discussion implies that a sequence of N intermediate iterations involves the solution of N+1 systems, comprising one solve with System 1 and N solves with System 2.

### 4.2.1 Updating the Required Vectors

This section concerns the details of how u,  $\mu$  and  $\lambda$  are updated. To simplify the discussion, the subscript k is suppressed whenever possible. With this notation, unbarred quantities belong to iteration k. Similarly, a bar over a quantity will indicate its updated value.

**Lemma 9** (Move to a new iterate.) Suppose that x is an iterate of an inertiacontrolling method. Let  $\bar{x} = x + \alpha p$ . The solution of  $W^T \bar{\lambda} = \bar{g}$ , where  $\bar{g} = g(\bar{x}) = g + \alpha H p$ , is related to the vector  $\lambda$  via the equations

$$\bar{\lambda}_E = \lambda_E - \alpha(a_t^T p)\mu_E$$
 and  $\bar{\lambda}_t = \begin{cases} (1 - \alpha)\lambda_t & \text{if } p = \sigma u; \\ \lambda_t - \alpha\mu_t & \text{if } p = u. \end{cases}$ 

**Proof.** In this lemma, the move from x to  $\bar{x}$  changes only the gradient (not the working set). The desired result can be obtained by substituting p and the relation  $Hu = -W^T \mu$  (from (4.24)) in the expression  $\bar{g} = g + \alpha H p$ .

Updates following the addition of a constraint (say,  $a_r$ ) to the working set use vectors z and  $\eta$  defined by the system

$$\begin{pmatrix} H & W^T \\ W & 0 \end{pmatrix} \begin{pmatrix} z \\ \eta \end{pmatrix} = \begin{pmatrix} a_r \\ 0 \end{pmatrix}, \tag{4.26}$$

i.e., z and  $\eta$  satisfy

$$Hz + A^{T}\eta_{E} + \eta_{t}a_{t} = a_{r}, \quad Az = 0 \quad \text{and} \quad a_{t}^{T}z = 0.$$
 (4.27)

The case when  $a_r$  can be added directly to W is considered first. Following the updates given in the next lemma, m increases by one and the "new"  $\lambda$  and  $\mu$  have one additional component.

**Lemma 10** (Constraint addition; independent case.) Let x denote an iterate of an inertia-controlling method. Assume that constraint  $a_r$  is to be added to the working set at x, where  $W^T$  and  $a_r$  are linearly independent. Let  $\rho = a_r^T u/a_r^T z$ . Then the vectors  $\bar{u}$  and  $\bar{\mu}$  defined by

$$\bar{u} = u - \rho z, \qquad \bar{\mu} = \begin{pmatrix} \mu - \rho \eta \\ \rho \end{pmatrix}$$
 (4.28)

satisfy

$$\begin{pmatrix} H & \bar{W}^T \\ \bar{W} & 0 \end{pmatrix} \begin{pmatrix} \bar{u} \\ \bar{\mu} \end{pmatrix} = \begin{pmatrix} 0 \\ e_t \end{pmatrix}. \tag{4.29}$$

**Proof.** When  $a_r$  and  $W^T$  are linearly independent, (4.27) shows that z must be nonzero. Since Wz = 0 and  $Z_w^T H Z_w$  is positive definite,  $a_r^T z = z^T H z > 0$ , so that  $\rho$  is well defined.

For any scalar  $\rho$ , (4.24) and (4.26) imply that

$$\begin{pmatrix}
H & W^T & a_r \\
W & 0 & 0 \\
a_r^T & 0 & 0
\end{pmatrix}
\begin{pmatrix}
u - \rho z \\
\mu - \rho \eta \\
\rho
\end{pmatrix} = \begin{pmatrix}
0 \\
e_t \\
a_r^T u - \rho a_r^T z
\end{pmatrix}.$$
(4.30)

The linear independence of  $a_r$  and  $W^T$  means that the solution vectors of (4.29) are unique. If  $\rho$  is chosen so that the last component of the right-hand side of (4.30) vanishes, then the  $\bar{u}$  and  $\bar{\mu}$  of (4.28) satisfy (4.29).

If  $Z^THZ$  is positive definite and  $W \neq A$ ,  $a_t$  can be deleted from W, and W then becomes A itself. The following lemma may be applied in two situations: when a constraint is deleted from the working set at a minimizer and the reduced Hessian remains positive definite after deletion; and at an intermediate iterate after a constraint has been added that makes  $Z^THZ$  positive definite.

**Lemma 11** (Deleting  $a_t$  from W.) Suppose that x is an iterate of an inertiacontrolling method,  $W \neq A$ , and  $Z^THZ$  is positive definite. Then the vector  $\bar{\lambda}$  is defined by

$$\bar{\lambda} = \lambda_E + \rho \mu_E, \quad where \quad \rho = -\frac{\lambda_t}{\mu_t},$$
 (4.31)

satisfies  $A^T \bar{\lambda} = g$ .

**Proof.** Let  $\lambda' = \lambda + \rho \mu$  for some scalar  $\rho$ . Substituting these values in  $W^T \lambda = g$ , yields

$$A^{T}(\lambda_{E} + \rho \mu_{E}) + a_{t}(\lambda_{t} + \rho \mu_{t}) = g.$$

It follows that  $A^T \bar{\lambda} = g$  will be satisfied by  $\lambda_E'$  if  $\lambda_t + \rho \mu_t = 0$ . It is permissible to delete  $a_t$  from W only if  $Z^T H Z$  is positive definite, which means that  $\mu_t < 0$ , and hence  $\rho$  is well defined.

Note that u and  $\mu$  are no longer needed to define the search direction after  $a_t$  has been removed.

The only remaining possibility occurs when  $a_r$ , the constraint to be added, is linearly dependent on  $W^T$ ; in this case, z=0 in (4.26). It follows from Lemma 8 that the iterate just reached must be a minimizer with respect to the working set composed of  $A^T$  and  $a_r$ , which means that  $a_t$  is no longer necessary. However, it is not possible to apply Lemma 11 because  $\mu_t$  may be zero. The following lemma gives an update that simultaneously removes  $a_t$  from W and adds  $a_r$  to the working set. After application of these updates,  $\bar{A}$  is the "real" working set at  $\bar{x}$ , and the algorithm either terminates or deletes a constraint (which cannot be  $a_r$ ).

**Lemma 12** (Constraint addition; dependent case.) Suppose that x is an intermediate iterate. Assume that  $a_r$  is to be added to the working set at x, and that  $a_r$  and  $W^T$  are linearly dependent. Let  $\bar{A}$  denote A with  $a_r^T$  as an additional row, and define  $\omega = \lambda_t/\eta_t$ . The vector  $\bar{\lambda}$  specified by

$$\bar{\lambda}_E = \lambda_E - \omega \eta_E, \quad \bar{\lambda}_a = \omega,$$
 (4.32)

where  $\bar{\lambda}_a$  denotes the component of  $\bar{\lambda}$  corresponding to  $a_r$ , satisfies  $\bar{W}^T\bar{\lambda}=g$ .

**Proof.** First, observe that linear dependence of  $W^T$  and  $a_r$  means that z=0. As the initial working set has full row rank, for an active-set QP algorithm of the form described, any constraint added to the working set must be linearly independent of the constraints in the working set. Hence  $a_r$  cannot be linearly dependent on  $A^T$ , which implies that  $\eta_t \neq 0$ . Lemma 8 tells us that x must be a subspace minimizer with respect to a working set. The desired results follow from substitution.

#### Algorithm 4.2.1. Convex Quadratic Programming.

```
Solve System 0 for p_0 and \lambda_0;
x \leftarrow x_0 + p_0;
subspace\_minimizer \leftarrow \mathbf{true}; \ \lambda \leftarrow \lambda_0;
repeat
      if subspace_minimizer then
              \lambda_t \leftarrow minimum \lambda;
              optimal \leftarrow (\lambda_t \geq 0);
              if optimal then stop;
               Solve System 1 for u and \mu;
              singular_H \leftarrow (\mu_t = 0);
      end
      p \leftarrow \text{ if } singular\_H \text{ then } u \text{ else } (\lambda_t/\mu_t)u \text{ end};
      \alpha_{\scriptscriptstyle B} \leftarrow \ \ maximum \ feasible \ step \ along \ p;
      \alpha \leftarrow \text{ if } singular\_H \text{ then } \alpha_B \text{ else } \min\{1, \alpha_B\} \text{ end};
      x \leftarrow x + \alpha p;
      \lambda \leftarrow \text{if } singular\_H \text{ then } \lambda - \alpha \mu \text{ else } \lambda - \alpha(\lambda_t/\mu_t)\mu \text{ end};
      subspace\_minimizer \leftarrow \lambda_t = 0;
      hit\_constraint \leftarrow (\alpha = \alpha_B);
      if hit_constraint then
               Solve System 2 for z and \eta;
              singular_{-}W \leftarrow (z=0);
             if singular_W then
                      Swap a_r and a_t;
                      \omega \leftarrow \lambda_t/\eta_t; \ \lambda_E \leftarrow \lambda_E - \omega \eta_E; \ \lambda_t \leftarrow \omega;
                      subspace\_minimizer \leftarrow \mathbf{true};
```

```
else

Add constraint with normal a_r;

Define \rho \leftarrow a_r^T u/a_r^T z;

u \leftarrow u - \rho z; v \leftarrow \begin{pmatrix} \mu - \rho \eta \\ \rho \end{pmatrix}; \lambda \leftarrow \begin{pmatrix} \lambda \\ 0 \end{pmatrix};

end;

else

Delete t-th row of W;

end;

until optimal;
```

## 4.3 Special Properties of the Standard Form

For the development of the Schur-complement (SC) method, the QP is assumed to be of the form

where H is positive semi-definite. The corresponding slack variable form is given by

minimize 
$$\psi(x) = c^T x + \frac{1}{2} x^T H x$$
,  
subject to  $Ax - s = b$ ,  $x \ge 0$ ,  $s \ge 0$ ,  $(4.33)$ 

where s are the slack variables. This form simplifies the notation used in the following sections, however, the results of these sections can easily be extended to the general form given in (2.1).

So far, we have discussed the role of the working set matrix W without particular attention to the computational advantages that arise when the constraints are in the standard form (4.33). Standard form allows the nonzero ("free") components of the search direction to be computed using a matrix whose column dimension is equal to the number of free variables (rather than the total number of variables). To formalize this idea, assume that W is associated with a working set containing only active constraints, and let  $n_{FR}$  denote the number of free variables

(i.e., corresponding to bounds not in W), and let the subscript "FR" denote the corresponding components of a vector or matrix. For example,  $A_{FR}$  denotes the  $m \times n_{FR}$  submatrix of columns of A corresponding to free variables. Similarly, the subscript "FX" means the components corresponding to fixed variables (i.e., those whose bounds are in the working set). (We shall henceforth switch freely between the terminologies of "working sets" and "free/fixed variables".)

Since the rows of (A - I) are linearly independent, a working set will include all the constraints Ax - s = b together with the gradients of a subset of the nonnegativity constraints. Hence, we can always find a permutation P such that

$$WP = \begin{pmatrix} A_{FR} & A_{FX} \\ 0 & I_{FX} \end{pmatrix}, \tag{4.34}$$

where  $A_{\it FR}$  and  $A_{\it FX}$  contain the columns of ( A-I ) corresponding to the free and fixed variables respectively. In the notation of Chapter 2,  $A_{\it FX}=N$  and  $A_{\it FR}=(B-S)$ .

Given this form of the working set, the symmetrically permuted version of System 1 can be written as

$$\left(egin{array}{cccc} H_{FR} & H_{OD} & A_{FR}^T & 0 \ H_{OD}^T & H_{FX} & A_{FX}^T & I_{FX} \ A_{FR} & A_{FX} & 0 & 0 \ 0 & I_{FX} & 0 & 0 \end{array}
ight) \left(egin{array}{c} u_{FR} \ u_{FX} \ \mu_E \ \mu_X \end{array}
ight) = \left(egin{array}{c} 0 \ 0 \ 0 \ e_t \end{array}
ight),$$

where  $H_{OD}$  is the matrix of off-diagonal mixed terms of the Hessian, and  $\mu_E$  and  $\mu_B$  are elements of  $\mu$  corresponding to the general and bound constraints respectively. Close inspection of these partitioned equations reveals that  $u_{FX} = e_t$  and  $\mu_B = -A_{FX}^T \mu_E - H_{OD}^T u_{FR} - h_t$ , where  $u_{FR}$  and  $\mu_E$  satisfy

$$\begin{pmatrix} H_{FR} & A_{FR}^T \\ A_{FR} & 0 \end{pmatrix} \begin{pmatrix} u_{FR} \\ \mu_E \end{pmatrix} = - \begin{pmatrix} h_t \\ a_t \end{pmatrix}. \tag{4.35}$$

This system, which is analogous to System 1, preserves the two-by-two block structure of the KKT matrix, but only involves the free variables.

Now we turn to System 2. The symmetrically permuted system is

$$\left(egin{array}{cccc} H_{FR} & H_{OD} & A_{FR}^T & 0 \ H_{OD}^T & H_{FX} & A_{FX}^T & I_{FX} \ A_{FR} & A_{FX} & 0 & 0 \ 0 & I_{FX} & 0 & 0 \end{array}
ight) \left(egin{array}{c} z_{FR} \ z_{FX} \ \eta_E \ \eta_X \end{array}
ight) = \left(egin{array}{c} e_r \ 0 \ 0 \ 0 \end{array}
ight),$$

where the elements of  $\eta_E$  and  $\eta_B$  match the general and bound constraints as above. These equations give  $z_{FX} = 0$  and  $\eta_B = -H_{OD}^T u_{FR} - A_{FX}^T \eta_E$ , where  $u_{FR}$  and  $\eta_E$  satisfy

$$\begin{pmatrix} H_{FR} & A_{FR}^T \\ A_{FR} & 0 \end{pmatrix} \begin{pmatrix} z_{FR} \\ \eta_E \end{pmatrix} = \begin{pmatrix} e_r \\ 0 \end{pmatrix}. \tag{4.36}$$

This is the "free-variable form" of System 2.

## 4.4 Schur Complement QP

Schur-complement QP methods are based on the properties of certain *block-bordered* linear systems. Consider the nonsingular block two-by-two system

$$\begin{pmatrix} K_0 & V \\ V^T & D \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \tag{4.37}$$

where  $K_0$  and D are symmetric. This system can be solved using factorizations of  $K_0$  and C, the Schur complement of  $K_0$ :

$$C \equiv D - V^T K_0^{-1} V, \tag{4.38}$$

(see, e.g., Bisschop and Meerhaus, [1, 2]; Gill et al., [17]). To show this, we write

$$\begin{pmatrix} K_0 & V \\ V^T & D \end{pmatrix} = \begin{pmatrix} K_0 & 0 \\ V^T & I \end{pmatrix} \begin{pmatrix} I & W \\ 0 & C \end{pmatrix},$$

where W satisfies  $K_0W = V$ . A simple calculation gives

$$\begin{pmatrix} K_0 & 0 \\ V^T & I \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \qquad \begin{pmatrix} I & W \\ 0 & C \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix},$$

and the following equations are solved in turn:

$$K_{0}z_{1} = f_{1}$$

$$z_{2} = f_{2} - V^{T}z_{1}$$

$$Cy_{2} = z_{2}$$

$$K_{0}y_{1} = f_{1} - Vy_{2} \text{ or } y_{1} = z_{1} - Wy_{2}$$

$$(4.39)$$

It will be shown in the next section that solutions of System 1 (4.35) and System 2 (4.36) can be defined in terms of a block two-by-two matrix of the form (4.37). Moreover, at each iteration, a column is added to V and a row and column are added to D. This results in the addition of a single row and column to the Schur complement C. To show this, we write the associated KKT system as

$$\begin{pmatrix} K_0 & \bar{V} \\ \bar{V}^T & \bar{D} \end{pmatrix}, \text{ where } \bar{V} = \begin{pmatrix} V & v \end{pmatrix} \text{ and } \bar{D} = \begin{pmatrix} D & d \\ d^T & \delta \end{pmatrix}. \tag{4.40}$$

(The definitions of v, d and  $\delta$  depend on the nature of the change in the working set.) The new Schur complement  $\bar{C}$  for (4.40) is given by

$$\bar{C} = \bar{D} - \bar{V}^T K_0^{-1} \bar{V} = \begin{pmatrix} D & d \\ d^T & \delta \end{pmatrix} - \begin{pmatrix} V^T \\ v^T \end{pmatrix} K_0^{-1} \begin{pmatrix} V & v \end{pmatrix}. \tag{4.41}$$

Comparison of this identity with (4.38) reveals that the Schur complement is bordered by a single row and column;

$$\bar{C} = \begin{pmatrix} C & c \\ c^T & \tau \end{pmatrix},\tag{4.42}$$

where

$$K_0 q = v, \qquad c = d - V^T q \quad \text{and} \quad \tau = \delta - v^T q.$$
 (4.43)

Note that a solve with  $K_0$  is needed to update C.

### 4.4.1 The Schur Complement Update

To illustrate the application of the Schur-complement method to convex QP, we consider a sequence of intermediate iterates, starting at a non-optimal subspace minimizer  $(x_0, s_0)$ . Let  $K_0$  denote the KKT matrix of free variables at  $(x_0, s_0)$ , with

$$K_0 = \begin{pmatrix} H_0 & A_0^T \\ A_0 & 0 \end{pmatrix},$$

where  $A_0$  and  $H_0$  denote the free rows and columns of (A - I) and H. If variable  $t_0$  is moved away from its bound at  $(x_0, s_0)$ , it is necessary to solve System 1 (4.35) at  $(x_0, s_0)$ , i.e.,

$$\begin{pmatrix} H_0 & A_0^T \\ A_0 & 0 \end{pmatrix} \begin{pmatrix} u_0 \\ \mu_0 \end{pmatrix} = - \begin{pmatrix} h_{t_0} \\ a_{t_0} \end{pmatrix},$$

where  $h_{t_0}$  and  $a_{t_0}$  denote the  $t_0$ -th columns of H and (A - I). The vector  $u_0$  is used to define  $p_0$ .

Assume that the next iterate  $(x_1, s_1)$  is intermediate, with variable  $r_1$  blocking at  $(x_1, s_1) = (x_0, s_0) + \alpha_0 p_0$ . In this case,  $u_1$  and  $\mu_1$  are found by updating the vectors  $u_0$  and  $\mu_0$  using  $z_1$  and  $\eta_1$  defined by System 2 (4.36), i.e.,

$$\begin{pmatrix} H_0 & A_0^T \\ A_0 & 0 \end{pmatrix} \begin{pmatrix} z_1 \\ \eta_1 \end{pmatrix} = \begin{pmatrix} e_{r_1} \\ 0 \end{pmatrix}.$$

Once  $u_1$  is known, the new iterate  $(x_2, s_2) = (x_1, s_1) + \alpha_1 p_1$  is calculated using the direction  $p_1$ .

So far, all the systems to be solved have been in terms of  $K_0$ . At  $(x_1, s_1)$ , however, the set of free variables will either increase or decrease, thereby increasing or decreasing the the dimension of the underlying KKT system changes. The two alternative cases will be considered separately.

First, assume that  $(x_2, s_2)$  is also intermediate, with variable  $r_2$  blocking. One obvious way to proceed would be to redefine the set of fixed and free variables and

solve System 2 (4.36) with right-hand-side  $e_{r_2}$  for  $z_2$  and  $\eta_2$ . This method would need to efficiently solve a KKT system that varies in composition and size as the set of fixed and free variables changes. In contrast, we now show that the special nature of these changes allows us to define an algorithm in which the solution of (4.35) and (4.36) may be obtained during k successive iterations using a fixed sparse factorization of  $K_0$ , and a dense factorization of the Schur complement of (at most) order k.

We return to the calculation of  $z_2$  and  $\eta_2$  from System 2 (4.36). Consider the system

$$\begin{pmatrix} H_0 & A_0^T & e_{r_1} \\ A_0 & 0 & 0 \\ e_{r_1}^T & 0 & 0 \end{pmatrix} \begin{pmatrix} z_2' \\ \eta_2' \\ \eta_{r_1}' \end{pmatrix} = \begin{pmatrix} e_{r_2} \\ 0 \\ 0 \end{pmatrix}.$$

Every component of  $z'_2$  is a component of  $z_2$  except the  $r_2$ th, which has been forced to be zero. The variable  $\eta'_{r_1}$  appears only in the  $r_1$ th equation, which is redundant. Observe that the matrix of this system has the form

$$K_1 \stackrel{\triangle}{=} \begin{pmatrix} K_0 & e_{r_1} \\ e_{r_1}^T & 0 \end{pmatrix}, \tag{4.44}$$

which has the bordered structure (4.37). Solutions with  $K_1$  can be determined using the Schur complement of  $K_0$  in  $K_1$ .

Once  $z_2$  and  $\eta_2$  are computed, they are used to define new vectors  $u_2$  and  $\mu_2$  and to define the Schur complement update for

$$K_2 = \begin{pmatrix} K_1 & e_{r_2} \\ e_{r_2}^T & 0 \end{pmatrix}$$

(cf. (4.41)). Subsequent intermediate iterates are treated the same way, i.e., after each step to an intermediate iterate, the KKT matrix is bordered by a row and column of the identity matrix.

Now suppose that  $(x_2, s_2) = (x_1, s_1) + \alpha_1 p_1$  is a subspace minimizer instead of an intermediate iterate. In this case, variable  $t_0$  is added to the list of free variables, which implies that the Schur complement for the bordered matrix

$$egin{pmatrix} H_0 & A_0^T & e_{r_1} & h_{t_0} \ A_0 & 0 & 0 & a_{t_0} \ e_{r_1}^T & 0 & 0 & 0 \ h_{t_0}^T & a_{t_0}^T & 0 & h_{t_0,t_0} \ \end{pmatrix}$$

is computed from the Schur complement of (4.44). Given a new variable  $t_2$  to be moved from its bound, the new values of u and  $\mu$  are determined from the system

$$\left(egin{array}{cccccc} H_0 & A_0^T & e_{r_1} & h_{t_0} \ A_0 & 0 & 0 & a_{t_0} \ e_{r_1}^T & 0 & 0 & 0 \ h_{t_0}^T & a_{t_0}^T & 0 & h_{t_0,t_0} \end{array}
ight) \left(egin{array}{c} u_2' \ \mu_2' \ \mu_{r_1}' \ u_{t_0}' \end{array}
ight) = - \left(egin{array}{c} (h_{t_2})_0 \ a_{t_2} \ 0 \ h_{t_0,t_2} \end{array}
ight),$$

where  $(h_{t_2})_0$  denotes the elements of the  $t_2$ th column of H that correspond to the list of free variables at  $(x_0, s_0)$ .

We have shown that at each iteration, the free-variable KKT system is bordered by a single row and column. When a variable is fixed on its bound, this column is a column of the identity. When a variable is added to the free list, the column is formed from the free elements of a row and column of H and a column of (A - I).

A typical iteration requires three solves with  $K_0$ : two solves to obtain the solution of System 1 or 2, and one solve to update the Schur complement. However, if the vectors of the form

$$K_0^{-1} \begin{pmatrix} h_t \\ a_t \end{pmatrix}$$
 and  $K_0^{-1} \begin{pmatrix} e_r \\ 0 \end{pmatrix}$ 

are stored as they are computed, only one solve with  $K_0$  is required at each step.

### 4.4.2 Algorithmic Details

When a variable  $(x,s)_j$  changes state, there are only three possible changes:

free 
$$\rightarrow$$
 fixed,  
fixed  $\rightarrow$   $t$ ,  
 $t \rightarrow$  free.

The notation  $\to t$  implies that  $(x,s)_j$  becomes the t-th variable, and  $t \to \text{implies}$  that the t-th variable is changing state.

Initially t = 0, so all the variables are either free or fixed. For all possible relative states to  $K_0$ , Table 4.1 indicates the effect on the size of C, and the value of t, when each of these states is encountered.

	Table	4.1:	The cl	nange in	value	of t	and	size	of (	C for	active-set	updates
--	-------	------	--------	----------	-------	------	-----	------	------	-------	------------	---------

	For $(x,s)_j$ initially free	size of $C$	value of $t$
1.	$free \rightarrow fixed$	increases by 1	no change
2.	free $\rightarrow$ fixed $\rightarrow t$	no change	$t \leftarrow j$
3.	free $\rightarrow$ fixed $\rightarrow t \rightarrow$ free	decreases by 1	$t \leftarrow 0$
	For $(x,s)_j$ initially fixed		
4.	fixed $\rightarrow t$	no change	$t \leftarrow j$
5.	fixed $\to t \to \text{free}$	increases by 1	$t \leftarrow 0$
6.	fixed $\rightarrow t \rightarrow \text{free} \rightarrow \text{fixed}$	decreases by 1	no change

If  $(x, s)_j$  hits its bound, and  $j \neq t$ , then a free variable is becoming fixed. If the variable was originally fixed (6), then the row and column associated with freeing the j-th variable can be deleted from C. If the j-th variable was originally free (1), then a row and column must be added to C. This corresponds to expanding V and D as given in (4.40), where, if the r-th free variable is being fixed,  $v = e_r$ , d = 0 and  $\delta = 0$ . In either case, there is no change to t.

At a stationary point, if  $(x, s)_j$  is to be freed, it is first held as the next variable to be deleted (fixed  $\to t$ , (2, 4)). If the current t = 0, as it is initially and after it has been reset, there is no change to C. Otherwise, there must be a corresponding  $t \to free$  change to first delete the current t-th variable. Depending on the status

of the t-th variable at  $(x_0, s_0)$ , the size of C either increases (5) or decreases (3) by an associated row and column. For an increase in the size of C, the extensions to V and D are given by by,

$$v = \begin{pmatrix} (h_t)_{FR} \\ a_t \end{pmatrix}, \tag{4.45}$$

where  $a_t$  is the t-th column of (A - I), and  $(h_t)_{FR}$  is defined by the free variables at the initial point  $(x_0, s_0)$ . The vector d is given by

$$d = (h_t)_{FR}, \tag{4.46}$$

where  $(h_t)_{FR}$  is defined by the variables freed during iterations  $1, \ldots, j-1$ . The scalar  $\delta = h_{tt}$ . In all cases, the value of t is updated to j,  $t \leftarrow j$ .

The update to C for the addition of a row and column is given by (4.42) and (4.43). The updated LU factors of C will be of the form

$$\bar{L} = \begin{pmatrix} L & 0 \\ l^T & 1 \end{pmatrix} \quad \text{and} \quad \bar{U} = \begin{pmatrix} U & u \\ 0 & \rho \end{pmatrix}, \tag{4.47}$$

where here l and u are the new row of L and column of U respectively. Setting  $\bar{L}\bar{U} = \bar{C}$ , substituting from (4.47) and comparing sides, indicates that l, u and  $\rho$  can be calculated by

$$Lu = c,$$

$$Ul = c,$$

$$\rho = \tau - l^{T}u.$$
(4.48)

Now consider the update to C that deletes a row and column. Let C be defined by

$$\begin{pmatrix}
C_{11} & c_1 & C_{12} \\
c_1^T & \gamma & c_2^T \\
C_{12}^T & c_2 & C_{22}
\end{pmatrix} = \begin{pmatrix}
L_{11} & & \\
l_1^T & 1 & \\
L_{21} & l_2 & L_{22}
\end{pmatrix} \begin{pmatrix}
U_{11} & u_1 & U_{12} \\
& \rho & u_2^T \\
& & U_{22}
\end{pmatrix}, (4.49)$$

and let the row and column to be deleted be associated with  $c_1$ ,  $c_2$  and  $\gamma$ . The updated LU factors of  $\bar{C}$  are given by

$$\bar{C} = \begin{pmatrix} C_{11} & C_{12} \\ C_{12}^T & C_{22} \end{pmatrix} = \begin{pmatrix} L_{11} \\ L_{21} & L_{22} \end{pmatrix} \begin{pmatrix} U_{11} & U_{12} \\ & \bar{U}_{22} \end{pmatrix}, \tag{4.50}$$

where  $\bar{U}_{22}$  satisfies

$$L_{22}\bar{U}_{22} = L_{22}U_{22} + l_2u_2^T. (4.51)$$

The implementation requires two extra vectors,  $i_0 \in \mathbb{R}^{n+m}$  defined by

$$(i_0)_j = \begin{cases} +1 & \text{if } (x,s)_j \text{ is free at } (x_0,s_0), \\ -1 & \text{if } (x,s)_j \text{ is fixed at } (x_0,s_0), \end{cases}$$

and  $i_{sc}$  with

$$(i_{sc})_j = \begin{cases} +r & \text{if } (x,s)_r \text{ was freed for column } j \text{ of } C, \\ -r & \text{if } (x,s)_r \text{ was fixed for column } j \text{ of } C, \end{cases}$$

for j = 1, ..., k, where the dimension of C is  $k \times k$ . If  $n_c$  is the maximum dimension of C allowed, then  $i_{sc} \in \mathbb{R}^{n_c}$ .

When  $(x,s)_r$  hits a bound, and C must be updated, a check can be done to see if  $r = |(i_{sc})_j|$  for some j. If not, then a new row and column is added to C, and

$$(i_{sc})_{k+1} = -r.$$

Otherwise, the j-th row and column of C are deleted, and the j-th element of  $i_{sc}$  is deleted as well. The value of t remains unchanged.

If the current point is a subspace minimizer (i.e., p = 0), then a check is made to see if  $t \neq 0$ . If t is nonzero, then a check is first made to see if  $t = |(i_{sc})_j|$  for some j. If  $j \neq 0$  then the j-th row and column of C are deleted, as is the j-th element of  $i_{sc}$ . If t is not part of the Schur complement (i.e., j = 0), then a row and column are added to C, and

$$(i_{sc})_{k+1} = +t.$$

In both cases, t is temporarily reset to 0.

At a subspace minimizer, if t = 0 (including after the update to free the t-th variable), the value of t needs to be updated. If the r-th variable is chosen to be the new t-th variable, then  $t \leftarrow r$ . A check can be made to see if  $r = |(i_{sc})_j|$  for some j. If  $j \neq 0$ , then the j-th element of  $i_{sc}$  can be ignored in extracting the solution of the linear systems. If j = 0, then  $i_{sc}$  is unaffected. There is no effect on C for setting the new t.

Then,  $i_0$  and  $i_{sc}$  can be used to reconstruct the solution of

$$\begin{pmatrix} H & W^T \\ W & 0 \end{pmatrix} \begin{pmatrix} u \\ \mu \end{pmatrix} = \begin{pmatrix} 0 \\ e_t \end{pmatrix}$$

from (4.37). The initial values of u and  $\mu$  can be set using  $i_0$  and  $y_1$ , then while stepping through  $i_{sc}$  the appropriate changes can be made using elements of  $y_2$  to overwrite elements of u and  $\mu$  depending on if  $i_{sc}$  is positive or negative. If  $(i_{sc})_j = t$ , then the j-th element of q is ignored. A similar approach can be used to unscramble the solution of  $System\ 2$ .

# 4.5 Using an $\ell_2$ Penalty Objective Function

For the SC method described in the previous sections, it was assumed that an initial subspace minimizer was available. Thus, a constraint was deleted at  $(x_0, s_0)$ . Of course, in general this will not be true. A system of the form (4.23) can be solved for a given  $(x_0, s_0)$ , and the solution will yield a search direction  $p_0$  such that  $(x_0, s_0) + p_0$  is a subspace minimizer. However, for problem (4.33) the point  $(x_0, s_0) + p_0$  may not be feasible. In this section, a method using a composite objective function is derived to address the case when  $(x_0, s_0) + p_0$  is not feasible.

A two-phase approach such as that used in SQOPT could be used, where the first phase minimizes the sum of infeasibilities. Since the first phase is a linear program, the solution is generally a vertex solution. For problems where the number of degrees of freedom is large, this can imply a large number of changes to the active set during the first subproblem. For an SC method this would be disastrous since the size of the dense LU factors of C usually increases for each change to the active set.

A method that avoids this disadvantage uses a composite objective function in which the objective function  $\psi(x)$  is augmented by a penalty term involving the constraint violations. This composite objective is of the form

$$\min_{x} \min_{v} \psi(x) + \rho \|v\|, \tag{4.52}$$

where  $\|.\|$  is an appropriate norm,  $\rho$  is a large positive constant and v represents the constraint violations of the linear constraints and variable bounds at x. The approach developed in this section is to use the SC method to minimize the composite objective function subject to the original constraints. If v=0 at some point, then the penalty term can be dropped. If the composite objective is minimized at a point where  $v \neq 0$ , then the original QP is infeasible or  $\rho$  must be increased.

#### 4.5.1 Selecting the Penalty Norm

As mentioned in Section 1.1.4, the method of SNOPT uses a composite objective function when the QP subproblem is infeasible or unbounded. The algorithm enters elastic mode, where the objective is modified as in (4.52), using the  $\ell_1$  norm for the constraint violations.

The general form for the KKT system of the modified subproblem is given by

$$\begin{pmatrix} H & 0 & W^T \\ 0 & 0 & I \\ W & I & 0 \end{pmatrix} \begin{pmatrix} p \\ p_v \\ -\lambda \end{pmatrix} = - \begin{pmatrix} g \\ \rho e \\ 0 \end{pmatrix}, \tag{4.53}$$

where  $p_v$  is the search direction for the constraint violations. The form of the KKT matrix in (4.53) implies that the working set matrix W is still linearly independent. In the case of SNOPT, where the composite objective is used when the algorithm enters elastic mode, the working set is already linearly independent.

As a step is taken along the QP search directions derived from (4.53), constraints change from being violated to being on one of their bounds. As the step increases, a constraint that moved onto one of its bounds will become satisfied. Thus, it is not always necessary to compute a new search direction. Instead, the search can continue along the same search direction, with the previously violated constraint now satisfied. This is repeated until a satisfied constraint is about to go infeasible, or until the minimizer of the composite objective is found along the search direction. A change to the working set only occurs for the variable fixed at the last step. The other variables go from being violated to satisfied, but remain free.

For illustration, consider the simple example of

$$\underset{x}{\text{minimize }} c^T x + \frac{1}{2} x^T H x, \quad \text{subject to } x \ge b_l,$$

where  $c^T = (1, 1, 1, 1), b_l = (0.8, 1.6, 2.4, 3.2)^T, \rho = 10$  and

$$H = 10^{-1} \times \begin{pmatrix} 4 & 3 & 2 & 1 \\ 3 & 4 & 3 & 2 \\ 2 & 3 & 4 & 3 \\ 1 & 2 & 3 & 4 \end{pmatrix}.$$

At  $x_0 = 0$ , all the bounds are violated. Let the search direction p = e, where e is a vector of all ones. The plot of the original objective and the  $\ell_1$  penalty objective along p are shown in Figure 4.1. The *break points*, i.e., the points where the derivative is discontinuous, of the  $\ell_1$  penalty function along p are evident as each bound becomes satisfied. When the final bound on  $x_4$  becomes satisfied, at  $\alpha = 3.2$ , the composite and original objective functions are the same. The  $\ell_1$  objective is minimized at the third break point, with  $\alpha = 2.4$ . The algorithm would continue the search along p up to this point, where the bound on  $x_3$  would be added to the working set. Both  $x_1$  and  $x_2$  would remain free, however, their associated bound constraints would no longer be violated. The remaining variable,  $x_4$ , remains free with its bound still violated.

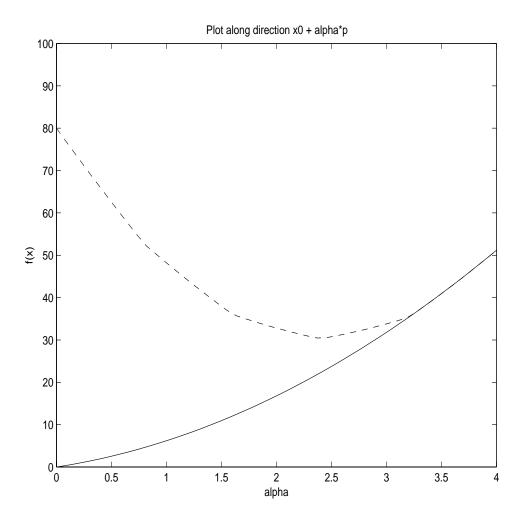

Figure 4.1: A plot of q(x) (solid line), and  $q(x) + ||v||_1$  (dashed line) along the search direction p. Note that once  $\alpha \geq 3.2$  all the bounds are satisfied and the two functions are the same. The penalty function is minimized where  $\alpha = 2.4$ , thus only the bound on  $(x)_3$  is added to the working set.

For the SC method, a phase 1 approach can be used to find an initial feasible point, and a composite objective used for infeasible or unbounded problems. This two-phase approach can be defined with the phase 1 Hessian consisting of an identity matrix associated with the sum of infeasibilities, and the phase 2 Hessian being H. However, this strategy has two major disadvantages for a SC method. First, the transition from phase 1 to phase 2 requires the initial  $K_0$  to be refactorized. Moreover, the phase 1 solution is often a vertex solution. Therefore, for problems with a large number of degrees of freedom, many working set changes are required to free variables from their bounds. This can cause the size of the Schur complement to grow very rapidly, forcing  $K_0$  to be factorized many times.

To avoid the disadvantages of a two-phase approach on an SC method, a composite objective can be used initially. Thus, the algorithm starts in elastic mode, without the benefit of a previously determined linearly independent working set. The modified subproblem, using the  $\ell_2$  penalty term, is given by

minimize 
$$c^T x + \frac{1}{2} x^T H x + \frac{\rho}{2} ||v||_2^2$$
,  
subject to  $Ax - s = b$ ,  $x \ge 0, \ s \ge 0, \ v \ge 0$ ,  $(4.54)$ 

where v represents the violations of the bounds on (x, s). The general form of the KKT system for problem (4.54) is given by

$$\begin{pmatrix} H & W^T \\ W & -\frac{1}{\rho}I \end{pmatrix} \begin{pmatrix} p \\ -\lambda \end{pmatrix} = -\begin{pmatrix} g \\ -v \end{pmatrix}. \tag{4.55}$$

Note that the search direction for the constraint violations is dependent on both v and  $\lambda$  (see Section 4.5.2). In addition, the constraints in the working set do not have to be linearly independent.

It can be shown for the  $\ell_1$  penalty function, that there exists a  $\bar{\rho}$ , such that for  $\rho > \bar{\rho}$ , the solution of the composite objective is a solution of the original problem. Thus, the  $\ell_1$  penalty function is often referred to as the "exact" penalty function. A disadvantage of the  $\ell_2$  penalty function is that the solutions with the penalty and

original objectives are only the same as  $\rho \to \infty$ . Therefore, the penalty parameter must be made very large to get an accurate solution of the original problem. If the working set is not full rank, the KKT matrix becomes more ill-conditioned as  $\rho \to \infty$ .

Another disadvantage of using the  $\ell_2$  penalty function is that minimizing the composite objective function for a given search direction requires updates to the Schur complement. In SNOPT, when using the  $\ell_1$  penalty function, no working set updates are required at the intermediate break-points. For the SC method, with the  $\ell_2$  penalty function, even though the search direction remains the same, updates to the Schur complement are required as each break-point is encountered (see Section 4.5.6). On the other hand, the  $\ell_2$  penalty function is a piecewise quadratic, with continuous first derivatives. Thus, the minimizer along a given search direction will usually occur between break points.

A picture of the different objective functions for the previous simple example is given in Figure 4.2. The continuity of the first derivatives of the  $\ell_2$  penalty function along p are evident. The  $\ell_2$  objective is minimized between the second and third break points. The algorithm continues along p until this point point is reached, at which no change is required to the working set. Both  $x_1$  and  $x_2$  would remain free, however, their associated bound constraints would no longer be violated. An update to the Schur complement is required as each variable changes from being violated to being satisfied. The remaining variables,  $x_3$  and  $x_4$ , remain free with their bounds violated.

# 4.5.2 Deriving the KKT System

The (n+m)-vector v of constraint violations is defined by

$$v = \begin{pmatrix} -I^x x \\ -I^s s \end{pmatrix}, \tag{4.56}$$

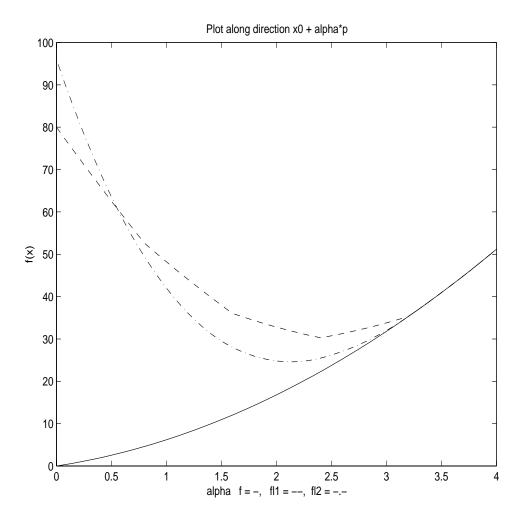

Figure 4.2: A plot of q(x) (solid line),  $q(x) + ||v||_1$  (dashed line) and  $q(x) + ||v||_2^2$  (dash-dot line) along the search direction p. Note that once  $\alpha \geq 3.2$  all the bounds are satisfied and all the functions are the same. The  $\ell_2$  penalty function is minimized between the second and third break points.

where  $I^x$  is a diagonal matrix whose entries are

$$I_{ii}^{x} = \begin{cases} 0 & \text{if } (x)_{i} \ge 0, \\ 1 & \text{if } (x)_{i} < 0. \end{cases}$$

The matrix  $I^s$  is similarly defined for the slack variables. Both  $I^x$  and  $I^s$  are symmetric and idempotent, thus the problem (4.54) can be stated more precisely as

minimize 
$$c^T x + \frac{1}{2} x^T H x + \frac{\rho}{2} x^T I^x x + \frac{\rho}{2} s^T I^s s$$
  
subject to  $Ax - s = b, \ x \ge 0, \ s \ge 0.$  (4.57)

Let  $(A - I)P = (A_{FR} \ A_{FX} \ I_v^s)$ , where P is a permutation matrix. The columns of  $A_{FR}$  correspond to variables such that  $x_i \neq 0$  and  $s_i > 0$ . If  $(x,s)_j = 0$  then the j-th column of (A - I) is in  $A_{FX}$ . The matrix  $I_v^s$  consists of the nonzero columns of  $I^s$  corresponding to the violated slacks  $(s_i < 0)$ . The working-set matrix W satisfies

$$WP = \left(egin{array}{ccc} A_{FR} & A_{FX} & -I_v^s \ 0 & I_{FX} & 0 \end{array}
ight),$$

where  $I_{FX}$  is an identity matrix with the same number of columns as  $A_{FX}$ . By an appropriate permutation, the KKT system for (4.57) is equivalent to

$$\begin{pmatrix} H_{FR} + \rho I_s^x & H_{OD} & 0 & A_{FR}^T & 0 \\ H_{OD}^T & H_{FX} & 0 & A_{FX}^T & I_{FX} \\ 0 & 0 & \rho I & (-I_v^s)^T & 0 \\ A_{FR} & A_{FX} & -I_v^s & 0 & 0 \\ 0 & I_{FX} & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} p_{FR} \\ p_{FX} \\ p_v \\ -\lambda_E \\ -\lambda_X \end{pmatrix} = - \begin{pmatrix} g_{FR} \\ g_{FX} \\ g_v \\ 0 \\ 0 \end{pmatrix}. \tag{4.58}$$

The vectors  $p_v$  and  $g_v$  are the search direction and objective gradient corresponding to the violations of the slack variables. The matrix  $I_s^x$  is defined similar to  $A_{FR}$  with columns from  $I^x$  and  $I^s$ . If  $(x)_i \neq 0$  then the *i*-th column of  $I^x$  is in  $I_s^x$ , and if  $(s)_j > 0$  then the *j*-th column of  $I_s^x$  is a zero column of appropriate dimension.

If the SC method is applied to (4.57), then the solution of *Systems*  $\theta$ , 1 and 2, and the updates to the Schur complement, must be defined for the KKT system (4.58).

#### 4.5.3 Solving System 0

The system (4.58) can be reduced to a KKT system in the free variables given by

$$\begin{pmatrix} H_{FR} + \rho I_s^x & A_{FR}^T \\ A_{FR} & -\frac{1}{\rho} I^s \end{pmatrix} \begin{pmatrix} p_{FR} \\ -\lambda_E \end{pmatrix} = -\begin{pmatrix} g_{FR} \\ I^s s \end{pmatrix}. \tag{4.59}$$

When the system is solved at the initial point for  $System \ \theta$ , the matrix in (4.59) is the initial  $K_0$  for the SC method. If  $p_{FR}$  and  $\lambda_E$  are the solution of (4.59) at the initial point, then the required  $\lambda_0$  can be recovered from  $\lambda_E$  and

$$\lambda_X = g_{FX} + H_{OD}^T p_{FR} - A_{FX}^T \lambda_E.$$

In addition,  $p_0$  can be obtained by permuting  $p_{FR}$ ,  $p_{FX}$  and  $p_v$ , where  $p_{FX} = 0$  and

$$p_v = -(I_v^s)^T (s + \frac{1}{\rho} \lambda_E).$$

# 4.5.4 Solving System 1

The solution of *System 1* is derived from the KKT based system (4.24). From the KKT system (4.58), the solution of *System 1* for problem (4.57) can be calculated by first solving

$$\begin{pmatrix} H_{FR} + \rho I_s^x & A_{FR}^T \\ A_{FR} & -\frac{1}{\rho} I^s \end{pmatrix} \begin{pmatrix} u_{FR} \\ \mu_E \end{pmatrix} = -\begin{pmatrix} (h_t)_{FR} \\ a_t \end{pmatrix}, \tag{4.60}$$

for  $u_{FR}$  and  $\mu_E$ . Then  $u_v$ ,  $u_{FX}$ ,  $(u)_t$ ,  $\mu_X$  and  $(\mu)_t$  are given by

$$u_{v} = -\frac{1}{\rho} (I_{v}^{s})^{T} \mu_{E},$$

$$\begin{pmatrix} u_{FX} \\ (u)_{t} \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

$$\begin{pmatrix} \mu_{X} \\ (\mu)_{t} \end{pmatrix} = -\begin{pmatrix} H_{OD}^{T} \\ (h_{t})_{FR}^{T} \end{pmatrix} u_{FR} - \begin{pmatrix} (h_{t})_{FX} \\ \hat{h}_{tt} \end{pmatrix} - \begin{pmatrix} A_{FX}^{T} \\ a_{t}^{T} \end{pmatrix} \mu_{E}.$$

$$(4.61)$$

where the definition of  $\hat{h}_{tt}$  depends on if the t-th variable is a slack variable ( $\hat{h}_{tt} = \rho$  or 0), or an x variable ( $\hat{h}_{tt} = h_{tt} + \rho I_{tt}^x$ ).

The reduced KKT system is not reformulated for each iteration. A system of the form (4.37) is solved at each iteration, where  $K_0$  is the matrix in (4.60) at the initial point  $(x_0, s_0)$ . For the SC method there were only two cases for updates to the Schur complement. Either a fixed variable was being freed, or a free variable was being fixed. The same basic two cases exist for the modified problem, however, the updates are dependent on whether the affected variable is an x variable or a slack variable. In the case of the slack variables, it also depends on if the free variable is violated or satisfied, or if the fixed variable is becoming violated or satisfied. The three distinct cases resulting from changes to the active set can be explicitly defined by

**CASE 1** – A fixed  $(x)_j$  is freed, becoming satisfied or violated; or a fixed  $(s)_j$  is freed, becoming satisfied.

**CASE 2** – A free, satisfied or violated,  $(x)_j$  is fixed; or a free satisfied  $(s)_j$  is fixed.

**CASE 3** – A fixed  $(s)_j$  is freed, becoming violated; or a free violated  $(s)_j$  is fixed.

The updates to Schur complement for each of the three cases are given in Section 4.5.6.

The vectors  $y_1$  and  $f_1$  in (4.37) for  $System\ 1$  are defined by  $y_1 = \begin{bmatrix} u_{FR} & \mu_E \end{bmatrix}^T$  and  $f_1 = \begin{bmatrix} (h_t)_{FR} & a_t \end{bmatrix}^T$ , where  $u_{FR}$ ,  $\mu_E$  and  $(h_t)_{FR}$  are all defined at the initial point. The elements of  $y_2$  and  $f_2$  are defined for the k-th iteration by

$$(y_2)_k = \begin{cases} (u)_j & \text{for CASE 1,} \\ (\mu)_j & \text{for CASE 2,} \\ (y_2)_j & \text{for CASE 3,} \end{cases}$$

and

$$(f_2)_k = \begin{cases} h_{jt} & \text{for CASE 1,} \\ 0 & \text{for CASE 2 and CASE 3.} \end{cases}$$

The element  $(y_2)_j$  is not part of the current  $u_{FR}$  or  $\mu_E$ , but is a working variable needed to define a rank-one update to  $I^s$  in SC form (see Section 4.5.6).

#### 4.5.5 Solving System 2

The solution of System 2 for problem (4.57) requires solving (4.25) with the matrix in (4.58). By appropriate permutation, the system is equivalent to

$$\begin{pmatrix} H_{FR} + \rho I_s^x & H_{OD} & (h_t)_{FR} & 0 & A_{FR}^T & 0 & 0 \\ H_{OD}^T & H_{FX} & (h_t)_{FX} & 0 & A_{FX}^T & I_{FX} & 0 \\ (h_t)_{FR}^T & (h_t)_{FX}^T & \hat{h}_{tt} & 0 & a_t^T & 0 & 1 \\ 0 & 0 & 0 & \rho I & (-I_v^s)^T & 0 & 0 \\ A_{FR} & A_{FX} & a_t & -I_v^s & 0 & 0 & 0 \\ 0 & 0 & 1_{FX} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} z_{FR} \\ z_{FX} \\ (z)_t \\ z_v \\ \eta_E \\ \eta_X \\ (\eta)_t \end{pmatrix} = \begin{pmatrix} e_{FR} \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

The right-hand side of this system is always a unit vector corresponding to the bound constraint of the free variable that has stepped onto its bound. Thus, if a violated slack variable has stepped onto its bound,  $e_v$  is a unit vector and  $e_{FR} = 0$ . Otherwise,  $e_v = 0$  and  $e_{FR}$  is a unit vector.

The associated reduced system for  $z_{FR}$  and  $\eta_E$  is

$$\begin{pmatrix} H_{FR} + \rho I_s^x & A_{FR}^T \\ A_{FR} & -\frac{1}{\rho} I^s \end{pmatrix} \begin{pmatrix} z_{FR} \\ \eta_E \end{pmatrix} = \begin{pmatrix} e_{FR} \\ \frac{1}{\rho} e_v \end{pmatrix}, \tag{4.62}$$

and  $z_v$ ,  $z_{FX}$ ,  $(z)_t$ ,  $\eta_X$  and  $(\eta)_t$  are computed via

$$z_{v} = \frac{1}{\rho} ((I_{v}^{s})^{T} \eta_{E} - e_{v})$$

$$\begin{pmatrix} z_{FX} \\ (z)_{t} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

$$\begin{pmatrix} \eta_{X} \\ (\eta)_{t} \end{pmatrix} = -\begin{pmatrix} H_{OD}^{T} \\ (h_{t})_{FR}^{T} \end{pmatrix} z_{FR} - \begin{pmatrix} A_{FX}^{T} \\ a_{t}^{T} \end{pmatrix} \eta_{E}.$$

$$(4.63)$$

The algorithm starts with (4.62) at the initial point, and a bordered system of the form (4.37) is used to solve subsequent systems. The vector  $y_1 = [z_{FR} \quad \eta_E]^T$  at  $(x_0, s_0)$ , and the elements of  $y_2$  for the k-th iteration defined by

$$(y_2)_k = \begin{cases} (z)_j & \text{for CASE 1,} \\ (\eta)_j & \text{for CASE 2,} \\ (y_2)_j & \text{for CASE 3.} \end{cases}$$

The right-hand side  $[f_1 \quad f_2]^T$  is always a unit vector, (or a multiple of a unit vector, i.e.  $\frac{1}{\rho}e_v$ ), corresponding to the variable that has hit its bound.

### 4.5.6 Updating the Schur Complement

When a variable changes state there are now five possible changes:

$$\begin{array}{cccc} \text{violated} & \rightarrow & \text{fixed}, \\ \text{satisfied} & \rightarrow & \text{fixed}, \\ \text{fixed} & \rightarrow & t, \\ t & \rightarrow & \text{violated}, \\ t & \rightarrow & \text{satisfied}. \end{array}$$

The notation  $\to t$  implies that  $(x,s)_j$  becomes the t-th variable, and  $t \to \text{implies}$  that the t-th variable is changing state. The notation violated represents a free variable that is outside its bounds, and similarly satisfied represents a free variable within its bounds.

Table 4.2 corresponds to the effect on the dimension of C, and value of t, for each of the relative states to  $K_0$ . Initially t = 0, so all variables are either violated, satisfied or fixed.

Table 4.2: The change in value of t and size of C for active-set updates

	For $(x,s)_j$ initially violated	size of $C$	value of $t$
1.	$violated \rightarrow fixed$	increases by 1	no change
2.	violated $\rightarrow$ fixed $\rightarrow t$	no change	$t \leftarrow j$
3.	violated $\rightarrow$ fixed $\rightarrow t \rightarrow$ violated	decreases by 1	$t \leftarrow 0$
4.	violated $\rightarrow$ fixed $\rightarrow t \rightarrow$ satisfied	increases by 1	$t \leftarrow 0$
5.	violated $\rightarrow$ fixed $\rightarrow$ t $\rightarrow$ satisfied $\rightarrow$ fixed	decreases by 1	no change
	For $(x,s)_j$ initially satisfied		
6.	satisfied $\rightarrow$ fixed	increases by 1	no change
7.	satisfied $\rightarrow$ fixed $\rightarrow t$	no change	$t \leftarrow j$
8.	satisfied $\rightarrow$ fixed $\rightarrow$ $t \rightarrow$ satisfied	decreases by 1	$t \leftarrow 0$
9.	satisfied $\rightarrow$ fixed $\rightarrow$ t $\rightarrow$ violated	increases by 1	$t \leftarrow 0$
10.	satisfied $\rightarrow$ fixed $\rightarrow$ t $\rightarrow$ violated $\rightarrow$ fixed	decreases by 1	no change
	For $(x,s)_j$ initially fixed		
11.	fixed $\to t$	no change	$t \leftarrow j$
12.	fixed $\to t \to \text{violated}$	increases by 1	$t \leftarrow 0$
13.	fixed $\rightarrow t \rightarrow \text{satisfied}$	increases by 1	$t \leftarrow 0$
14.	fixed $\rightarrow t \rightarrow \text{violated} \rightarrow \text{fixed}$	decreases by 1	no change
15.	fixed $\rightarrow t \rightarrow \text{satisfied} \rightarrow \text{fixed}$	decreases by 1	no change

If  $(x,s)_j$  hits its bound, and  $j \neq t$ , then either a violated or satisfied free variable is becoming fixed. If the variable was previously fixed (5, 10, 14, 15), then the row and column associated with freeing the j-th variable can be deleted from C. If the j-th variable was originally free, then a row and column must be added to C. For a satisfied variable (6), or a violated  $(x)_j$   $(1, CASE\ 2)$ , the corresponding expansion to V and D given by (4.40) is defined by  $v = e_r$ , d = 0 and  $\delta = 0$ , where

the r-th variable is being freed. If  $(x,s)_j$  corresponds to a *violated* slack that is becoming fixed (1, CASE 3), then the update to V and D is given by

$$v = \frac{1}{\sqrt{\rho}} e_r, \tag{4.64}$$

with d = 0 and  $\delta = -1$ . For all cases of a free variable becoming fixed, there is no change to t.

As before, if  $(x,s)_j$  is to be freed at a stationary point, it is first held as the next variable to be deleted (fixed  $\to t$ , (2, 7, 11)). If the current t = 0, there is again no change to C. Otherwise, there must be a corresponding  $t \to violated$  (3, 9, 12), or  $t \to satisfied$  (4, 8, 13), to first delete the current t-th variable. If the t-th variable is returning to the state it had at  $(x_0, s_0)$ , then C decreases in size by a row and column (3, 8). However, if the t-th variable was originally fixed (12, 13), or if the new state differs from the state at  $(x_0, s_0)$  (4, 9), then C increases by a row and column. The definition of v, d and  $\delta$  for the update depend on if the t-th variable is in x or s, and if it is becoming satisfied or violated.

If the t-variable is becoming satisfied, then v and d are given by (4.45) and (4.46) respectively, and the scalar is defined by  $\delta = h_{tt}$  as before. If  $(x, s)_t = (x)_t$ , and  $(x)_t$  is becoming violated, then v and d are also defined by (4.45) and (4.46), but  $\delta = h_{tt} + \rho$ . Finally, if the t-th variable is a slack that is becoming violated, then d = 0, v is given by (4.64) and  $\delta = 1$ . The value of t is updated to j,  $t \leftarrow j$ , for all cases.

# 4.5.7 Algorithmic Details

The updates for adding and deleting rows and columns of C are the same as those given in Sections 4.4.1–4.4.2.

For the  $\ell_2$  formulation, the implementation requires three extra vectors instead

of the two needed in Section 4.4.2. These are defined as  $i_0 \in \mathbb{R}^{n+m}$  with

$$(i_0)_j = \begin{cases} +1 & \text{if } (x,s)_j \text{ is satisfied at } (x_0,s_0), \\ 0 & \text{if } (x,s)_j \text{ is fixed at } (x_0,s_0), \\ -1 & \text{if } (x,s)_j \text{ is violated at } (x_0,s_0), \end{cases}$$

and  $i_{\scriptscriptstyle FR}^{sc}$  with

$$(i_{\mathit{FR}}^{\mathit{sc}})_j = \left\{ \begin{array}{ll} +r & \text{if} \quad (x,s)_r \quad \text{was becoming satisfied for column} \quad j \quad \text{of} \quad C, \\ -r & \text{if} \quad (x,s)_r \quad \text{was becoming violated for column} \quad j \quad \text{of} \quad C, \\ 0 & \text{otherwise}, \end{array} \right.$$

and  $i_{FX}^{sc}$  with

$$(i_{FX}^{sc})_j = \begin{cases} +r & \text{if } (x,s)_r \text{ was fixed from being satisfied for} \\ & \text{column } j \text{ of } C, \\ -r & \text{if } (x,s)_r \text{ was fixed from being violated for} \\ & \text{column } j \text{ of } C, \\ 0 & \text{otherwise,} \end{cases}$$

for  $j=1,\ldots,k$ , where the dimension of C is  $k\times k$ . If  $n_c$  is the maximum dimension of C allowed, then  $i_{FR}^{sc}\in I\!\!R^{n_c}$  and  $i_{FX}^{sc}\in I\!\!R^{n_c}$ . Here, the subscripts FR and FX do not refer to a partition of the same vector, instead  $i_{FR}^{sc}$  and  $i_{FX}^{sc}$  are distinct vectors.

To update C when  $(x,s)_r$  hits a bound  $(r \neq t)$ , a check is made to see if  $r = (i_{FR}^{sc})_j$  for some j. If not, then a new row and column is added to C, and

$$\begin{aligned} &(i^{sc}_{FR})_{k+1} &=& 0, \\ &(i^{sc}_{FX})_{k+1} &=& \left\{ \begin{array}{ll} +r & \text{if} & (x,s)_r & \text{was satisfied}, \\ -r & \text{if} & (x,s)_r & \text{was violated}. \end{array} \right.$$

As mentioned above, the row and column added depend on if  $(x,s)_r$  was a violated slack (r > n and  $(x,s)_r < 0$ ). This case is part of CASE 3 defined in Section 4.5.4, therefore  $q_{k+1}$  is a dummy variable and will be ignored in extracting the solution of the linear system. If  $j \neq 0$ , the j-th row and column of C are deleted, and the j-th element of  $i_{FR}^{sc}$  and  $i_{FX}^{sc}$  are deleted as well. The value of t remains unchanged.

If the current point is a subspace minimizer, a check is made to see if  $t \neq 0$ . If t is nonzero, a check is made to see if  $t = |(i_{FX}^{sc})_j|$  for some j. If j = 0, or if  $j \neq 0$  and  $(i_{FX}^{sc})_j$  and  $(i_0)_t$  are of opposite sign, then a row and column is added to C, and

$$(i_{FR}^{sc})_{k+1} = \begin{cases} +t & \text{if } (x,s)_t \text{ is becoming satisfied,} \\ -t & \text{if } (x,s)_t \text{ is becoming violated.} \end{cases}$$
  
 $(i_{FR}^{sc})_{k+1} = 0,$ 

The row and column added to C will depend on if t is a slack (t > n) that is becoming violated. This case also corresponds to CASE 3 defined in Section 4.5.4, thus  $q_{k+1}$  is a dummy variable and will be ignored. If  $j \neq 0$ , and  $(i_{FX}^{sc})_j$  and  $(i_0)_t$  have the same sign, the j-th row and column of C can be deleted, as well as the j-th elements of  $i_{FX}^{sc}$  and  $i_{FR}^{sc}$ .

When t = 0 at a subspace minimizer (including after the update to free the t-th variable), the value of t is reset to r ( $t \leftarrow r$ ). A check is made to see if  $r = |(i_{FX}^{sc})_j|$  for some j. If  $j \neq 0$  then  $(i_{FX}^{sc})_j$  is ignored in extracting the solution of the linear systems. Otherwise,  $i_{FX}^{sc}$  is unaffected. There is no update to C for reseting the value of t.

To extract the correct u and  $\mu$ , the initial values can be set using  $i_0$  and  $y_1$ . By stepping through  $i_{FX}^{sc}$ , the appropriate changes can be made to  $\mu$ . If  $i_{FX}^{sc} = 0$ , or  $(i_{FX}^{sc})_k < 0$  and  $|(i_{FX}^{sc})_k| > n$ , then  $(y_2)_k$  is ignored in updating  $\mu$ . Similarly, u can be updated by stepping through  $i_{FR}^{sc}$ . If  $(i_{FR}^{sc})_k = 0$ , or  $(i_{FR}^{sc})_k < 0$  and  $|(i_{FR}^{sc})_k| > n$ , then  $(y_2)_k$  is ignored. Additionally, if  $|(i_{FR}^{sc})_k| = t$ , then the k-th element of q is ignored. A similar approach can used to unscramble the solution of System~2.
