#### Abstract

Obtaining a graph from any given graph is a popular area of research in Graph Theory. Concept of Total Graph falls under this category. All the vertex-vertex adjacency, vertexedge incidence and edge-edge incidence relations are considered in the formation of the Total Graph. For a finite simple connected graph $\mathrm{G}, \mathrm{T}(\mathrm{G})$ can be decomposed into G and complete subgraphs of order equal to the degrees of each of the vertices in G. Also, T(G) can be decomposed into disjoint union of $\mathrm{L}(\mathrm{G})$ and q copies of $\mathrm{C}_{3}$, where q is the size of G .

Keywords: Degree sequence, Total Graph, Line Graph, Incidence Graph.

## 1. Introduction

We consider a graph $\mathrm{G}(p, q)$ with $p$ vertices and $q$ edges which is simple, connected, undirected and finite. Here, $p$ and $q$ are respectively called the order and size of G. Let $v$ be a vertex of G . The number of edges incident with $v$ is known as the degree of $v$, denoted by $\operatorname{deg}_{\mathrm{G}}(v)$, or merely by $\operatorname{deg}(v)$.[Chartrand, 2006] If the degrees of the vertices of a graph G are listed in a non-increasing sequence S , then S is called the degree sequence of G. For a graph G, obtaining edge disjoint sub-graphs (i.e. intersection of the edge set of all the sub-graphs is empty) whose union is the actual graph $G$ is called decomposition of the given graph $G$. Line Graph, $\mathrm{L}(\mathrm{G})$, of undirected graph G is a graph that represents the adjacencies between the edges of G. Given a graph G, each vertex of $L(G)$ represents an edge of $G$ and two vertices of $L(G)$ are adjacent if and only if their corresponding edges are adjacent in G. An Incidence Graph, $\mathrm{I}(\mathrm{G})$, is a graph whose vertices represent vertices and edges in G. Two vertices in $\mathrm{I}(\mathrm{G})$ are adjacent if and only if there is a vertex-edge incidence in G. Total Graph of a graph G, denoted by $T(G)$, is a graph whose vertices are represented by each vertex and each edge of G . There is an edge between two vertices in $T(G)$ if and only if there is edge-edge adjacency or edgevertex incidence or vertex-vertex adjacency in G. [West, 2002 and Harary, 2001]

We know that $\mathrm{T}(\mathrm{G})$ is isomorphic to the square of the subdivision graph $\mathrm{S}(\mathrm{G})$.
i.e. $\mathbf{T}(\mathbf{G}) \approx[\mathbf{S}(\mathbf{G})]^{2}$.[Harary, 2001]

But we also know that $\mathrm{S}(\mathrm{G}) \approx \mathrm{I}(\mathrm{G})$.
Hence, $T(G)$ is isomorphic to the square of the incidence graph $I(G)$.
i.e. $\mathbf{T}(\mathbf{G}) \approx[\mathbf{I}(\mathbf{G})]^{2}$

From the definition of total graph we can also define the total graph as the disjoint union of given graph, line graph and incidence graph.
i.e. $\mathbf{T}(\mathbf{G})=\mathbf{G} \cup \boldsymbol{L}(\boldsymbol{G}) \cup I(\boldsymbol{G})$

This is possible because in $T(G)$ vertex-vertex adjacency will give us $G$ itself, edge-edge adjacency gives us line graph of $G$, denoted by $L(G)$ and vertex-edge incidence will give
us incidence graph of $G$, denoted by $I(G)$. From the definition of total graph $G$, it is obvious that $\mathrm{L}(\mathrm{G})$ and $\mathrm{I}(\mathrm{G})$ in $\mathrm{T}(\mathrm{G})$ are disjoint.

## 2. Decomposition of $T(G)$ into $G$ and $K_{n}$ 's

Let $\mathrm{K} n$ denote a complete graph of $n$ vertices. Every edge in $G$ becomes a $K_{3}$ in $T(G)$. If we explore this phenomenon, we obtain the following result.

Theorem 2.1. Let $G$ be an undirected simple finite graph. Total Graph of $G$ can be decomposed into $G$ and $K_{d_{i}+:}$ 's, where d $\mathrm{d}_{\mathrm{i}}$ 's are degrees of each of the vertices in G. i.e. $T(G)$ $=G \mathrm{U} \mathrm{K}_{\mathrm{d} 1+1} \mathrm{U} \mathrm{K}_{\mathrm{d} 2+1} \mathrm{U} \ldots \ldots . . \mathrm{U} \mathrm{K}_{\mathrm{dn}+1}$, where $\mathrm{d}_{i}$ 's are degrees of each vertex in $G$.

Proof: Since $T(G)$ is the total graph of $G$, every vertex in $T(G)$ is represented by either a vertex or an edge in $G$. Two vertices in $T(G)$ are adjacent if and only if there is a corresponding vertex-vertex adjacency or edge-edge adjacency or an edge-vertex incidence in G. Now, the vertex-vertex adjacency in $G$ will give exactly the same copy of $G$ in $T(G)$. We also know that for each vertex-edge incidence and edge-edge adjacency in $G$, there exists an edge in $T(G)$.
Let $v_{1}$ be an arbitrary vertex in G with degree $d_{1}$.
So $v_{1}$ is incident with $d_{1}$ edges.
Let $\mathrm{e}_{1}, \mathrm{e}_{2} \ldots \ldots . \mathrm{e}_{\mathrm{d} 1}$ be these edges.
i.e., all these $\mathrm{e}_{\mathrm{i}}$ 's are incident with $v_{1}$. Hence in $\mathrm{T}(\mathrm{G})$, a vertex corresponding to $v_{1}$ is adjacent to all vertices corresponding to $\mathrm{e}_{\mathrm{i} \text { 's }}$.
Since in G, all $\mathrm{e}_{\mathrm{i}}$ 's are incident to $v_{1}$, obviously all $\mathrm{e}_{\mathrm{i}}$ 's are adjacent with each other.
Hence all $e_{i}$ 's will form a complete graph with $d_{i}$ vertices in $T(G)$.
But all $\mathrm{e}_{\mathrm{i}}$ 's are incident with $v_{1}$ and hence with the addition of the corresponding vertex in $T(G)$ to the already formed complete graph, the new complete graph is with $d_{1}+1$ vertices. i.e. $K_{d 1+1}$ is formed in $T(G)$.

Since $v_{1}$ is arbitrary, it is true for all vertices.
Now we have to show that all such complete graphs are disjoint.
Let $w$ be an edge common to $\mathrm{K}_{\mathrm{d} 1+1}$ and $\mathrm{K}_{\mathrm{d} 2+1}$ in $\mathrm{T}(\mathrm{G})$.
i.e., $w$ is there in $\mathrm{K}_{\mathrm{d} 1+1}$ and $w$ is also there in $\mathrm{K}_{\mathrm{d} 2+1}$.

Hence the end vertices of $w$ must be in both $\mathrm{K}_{\mathrm{d} 1+1}$ and $\mathrm{K}_{\mathrm{d} 2+1}$.
Let $w=\mathrm{e}_{1} \mathrm{e}_{2}$.
We know that $e_{1}$ and $e_{2}$ are adjacent in $T(G)$ since their corresponding edges are incident with some $\mathrm{v}_{1}$ in G .
Hence they are adjacent in $\mathrm{K}_{\mathrm{d} 1+1}$.
We know that since $w$ is also in $\mathrm{K}_{\mathrm{d} 2+1}$ and the corresponding vertices of $\mathrm{e}_{1}$ and $\mathrm{e}_{2}$ are adjacent in $G$, which means they are incident with another vertex other than $\mathrm{v}_{1}$.
Let it be $\mathrm{v}_{2}$.
Therefore $e_{1}$ and $e_{2}$ are incident with $v_{1}$ and $v_{2}$.
But this will lead to a multiple edge in G .
It is a contradiction, since $G$ is a simple graph.
Hence all the complete graphs in $T(G)$ are disjoint.
Hence we can decompose $T(G)$ into disjoint union of $G$ and $p$ complete graphs with di+1 vertices, where $\mathrm{d} i$ is the degree of each of the $p$ vertices in G .
Hence the proof.
Corollary 2.1.1. Let $K_{n}$ be a complete graph with $n$ vertices. Then $T\left(K_{n}\right)=$ $\bigcup_{i=1}^{n+1} K_{n_{i}} K_{n i}$ 's are copies of $K_{n}$.

Proof: From Theorem 2.1 we get, $T(G)=G U K_{d 1+1} U_{K d 2+1} U \ldots \ldots \ldots . U_{K d n+1}$, where $d_{i}$ 's are degrees of the vertices in $K_{n}$.
There are $n$ vertices in $K_{n}$ all of degree $n-1$.
i.e. $d_{i}=n-1$

Hence
$\mathrm{T}(\mathrm{G})=\mathrm{G} \mathrm{U} \mathrm{K}_{\mathrm{n}-1+1} \mathrm{U} \mathrm{K}_{\mathrm{n}-1+1} \mathrm{U} \ldots \ldots . . . \mathrm{U} \mathrm{K}_{\mathrm{n}-1+1}$
$T(G)=G^{\prime} U K_{n} U K_{n} U \ldots \ldots \ldots . . U K_{n}$.
So $T(G)$ can be decomposed into $G$ and union of $n$ copies $K_{n}$. Here $G$ is $K_{n}$.
Therefore $T(G)$ can be decomposed into union of $(n+1) K_{n}$ 's.
i.e., $T\left(K_{n}\right)=\bigcup_{i=1}^{n+1} K_{v_{i}}$, where $K_{n i}$ 's are copies of $K_{n}$.

Hence the proof.

## 3. Decomposition of $T(G)$ into $L(G)$ and $C_{3}$ 's

We know that total graph of any graph is the disjoint union of line graph, incidence graph of the given graph and the given graph itself. The edge-vertex incidence of each edge in $G$ is producing a $C_{3}$ in $T(G)$. It is seen that number of these $C_{3}$ 's can be found out. It is described in the next theorem.

Theorem 3.1. Let $G(p, q)$ be a simple undirected finite simple graph. Then $T(G)$ can be decomposed into $L(G)$ and $q$ copies of $\mathrm{C}_{3}$.

Proof: Let $G(p, q)$ be the given Graph. The total graph of $G$ is the disjoint union of $G$ and the line graph of $G$ and incidence graph of $G$.
i.e. $\mathrm{T}(\mathrm{G})=\mathrm{G} \cup L(G) \cup I(G)$ where $\mathrm{G}, \mathrm{L}(\mathrm{G})$ and $\mathrm{I}(\mathrm{G})$ are disjoint.

Clearly, $T(G)$ contains $L(G)$.
So when we remove $L(G)$ from $T(G)$ what is remaining $T(G)$ is $G U I(G)$.
Let $e=u v$ be an edge in G.
Hence $e$ will become a vertex in $\mathrm{I}(\mathrm{G})$ and will be incident with $u$ and $v$.
Therefore $e u$ and $e v$ will be two distinct edges in $\mathrm{I}(\mathrm{G})$.
Evidently in GU I(G), e-u-v-e will form $\mathrm{C}_{3}$.
Since $e$ is arbitrary, for each edge in $G$ we get a new copy of $\mathrm{C}_{3}$.
Since $G$ contains $q$ edges, we get $q$ copies of $C_{3}$.
Thus $\mathrm{T}(\mathrm{G})$ can be decomposed into $\mathrm{L}(\mathrm{G})$ and q copies of $\mathrm{C}_{3}$.
Hence the proof.
Corollary 3.1.1. Let $C_{n}$ be the cycle with $n$ vertices, then $T\left(C_{n}\right)$ can be decomposed into $\mathrm{C}_{\mathrm{n}}$ and $n$ copies of $\mathrm{C}_{3}$.

Proof: The proof is direct from the Theorem 3.1.
Here, G is $\mathrm{C} n$. $\mathrm{C} n$ has $n$ edges.
Also, $L\left(\mathrm{C}_{\mathrm{n}}\right)=\mathrm{C}_{\mathrm{n}}$.
Hence from the above theorem we can conclude that $T\left(C_{n}\right)$ can be decomposed into $C_{n}$ and $n$ copies of $\mathrm{C}_{3}$.
Hence the proof.

## 4. Conclusion

In this paper we had concentrated on decomposition of total graphs. The results that we discussed in decomposition of total graph are $T(G)=G U K_{d 1} U K_{d 2} U \ldots \ldots . . U K_{d n}$. and $\mathrm{T}(\mathrm{G}(\mathrm{p}, \mathrm{q}))=\mathrm{L}(\mathrm{G}) \mathrm{Uq} \mathrm{C}_{3}$. There is a lot of scope for the further study of decomposition of total graphs of some graph operations like Cartesian product, tensor product etc.
