# Gradient Flow Algorithm for Unconstrained Optimization 

Neculai Andrei ${ }^{1}$

#### Abstract

The gradient flow approach for unconstrained optimization is presented. The idea of this approach is that for an unconstrained optimization problem an ordinary differential equation to associate. Fundamentally this is a gradient system based on the first order optimality conditions of the problem. Using a discretization scheme, based on a two level implicit time discretization technique, with a splitting parameter $\theta \in[0,1]$, an algorithm is obtained. The convergence of this algorithm is analyzed and it is shown that this is linearly convergent when $0 \leq \theta<1$ and quadratically convergent when $\theta=1$ and the integration step is sufficiently large. At every step a linear algebraic system is solved, but no linear search is required. Numerical experiments on a limited number of test functions show that this approach based on integration of a gradient system is more robust and even superior to the Newton's method.

Key words. Unconstrained optimization, gradient flow method, quadratic convergence.

## 1. Introduction

Unconstrained optimization, expressed as $\min f(x)$, where $f(x)$ is a real function, is one of the most active area in optimization community, virtually appearing in every human activity. For solving these problems many efficient methods have been suggested. Excellent presentations of these methods can be found, for example, in (Refs. 1-5). The most useful algorithms classify in: the conjugate gradient method and its variants, the Newton method and its extensions, the BFGS variable metric method and its limited memory variants, the truncated Newton method and the Nelder-Mead simplex method. All these methods consider iterations of the form

$$
x_{k+1}=x_{k}+\lambda_{k} d_{k}
$$

where $d_{k}$ is a descent search direction and $\lambda_{k}$ is a steplength obtained by a one-dimensional search. The conjugate - gradient methods consider the search direction as $d_{k}=-\nabla f\left(x_{k}\right)+$ $\beta_{k} d_{k-1}$, where the scalar $\beta_{k}$ is chosen in such a manner that the method reduces to the linear conjugate gradient when the function is quadratic and the line search is exact. The rest of methods defines the search direction by $d_{k}=-B_{k}^{-1} \nabla f\left(x_{k}\right)$, where $B_{k}$ is a nonsingular symmetric matrix. Mainly, the matrix $B_{k}$ is selected as: $B_{k}=I$ (the steepest descent method), $B_{k}=\nabla^{2} f\left(x_{k}\right)$ (the Newton's method) or an approximation of the Hessian $\nabla^{2} f\left(x_{k}\right)$ (BFGS, DFP, SR1 etc.).

[^0]Other methods, different from those above mentioned, are the gradient flow methods, known as stable barrier-projection and barrier-Newton methods, which have been introduced for the first time by Evtushenko (Refs. 6,7) and by Evtushenko and Zhadan (Refs. 8-10). Convergence of these methods via Lyapunov functions has been considered by Smirnov (Ref. 10). Recently, improvements and some computational experience with these methods have been considered by Wang, Yang and Teo (Ref. 12). Basically, in this approach a constrained optimization problem is reformulated as an ordinary differential equation (ODE) in such a way that the solution of this ODE converges to an equilibrium point of the optimization problem as parameter $t$ from the ODE goes to $\infty$.

In this paper, a gradient flow approach for unconstrained optimization is proposed. To a general unconstrained optimization problem an ODE is associated. Basically, this ODE is a gradient system. For integration of this ODE a discretization scheme, based on a two level implicit time discretization scheme with a splitting parameter $\theta$ is proposed. It is shown that the solution of this discretized gradient flow equation converges to a local minimum of the original problem, either linearly or quadratically according to the choice of $\theta$ and of the time step size of the series of the discretization time points. When $\theta=1$ and the time step size tends to $\infty$, then the corresponding algorithm is quadratically convergent.

The structure of the paper is as follows. Section 2 is dedicated to present the idea of the gradient flow approach for unconstrained optimization. In section 3 we present the corresponding gradient flow algorithm, as well as its convergence analysis. Some numerical experiments and comparisons with the Newton method with backtracking are given in section 4.

## 2. The gradient flow approach for unconstrained optimization

Consider the following unconstrained optimization problem

$$
\begin{equation*}
\min f(x) \tag{1}
\end{equation*}
$$

where $x \in R^{n}$ and $f: R^{n} \rightarrow R$ is a function assumed to be twice continuous differentiable. As we know, a necessary condition for the point $x^{*}$ be an optimal solution for (1) is:

$$
\begin{equation*}
\nabla f\left(x^{*}\right)=0 \tag{2}
\end{equation*}
$$

This is a system of $n$ nonlinear equations, which must be solved to get the optimal solution $x^{*}$. In order to fulfill this optimality condition the following continuous gradient flow reformulation of the problem is suggested: solve the following ordinary differential equation:

$$
\begin{equation*}
\frac{d x(t)}{d t}=-\nabla f(x(t)) \tag{3}
\end{equation*}
$$

with the initial condition

$$
\begin{equation*}
x(0)=x_{0} . \tag{4}
\end{equation*}
$$

The following theorem gives the convergence result of the system (3) initialized with (4).
Theorem 2.1. Consider that $x^{*}$ is a point satisfying (2). Suppose that $\nabla^{2} f\left(x^{*}\right)$ is positive definite. If $x_{0}$ is close enough to $x^{*}$, then $x(t)$, solution of (3), tends to $x^{*}$ as $t$ goes to $\infty$.

Proof. The system (3) can be written as

$$
\dot{x}=\Phi(x)
$$

where $\Phi(x)=-\nabla f(x)$. To show that $x^{*}$ is an assymptotically stable point for (3) we shall consider the Poincaré - Lyapunov theory (Ref. 13). According to this theory, $x^{*}$ is an asymptotically stable point for the nonlinear differential equation system $\dot{x}=\Phi(x)$ if $\Phi(x)$ is continuously differentiable and the linearized system

$$
\dot{y}=\nabla \Phi\left(x^{*}\right) y,
$$

where $y=x-x^{*}$, is exponentially stable, i.e. all eigenvalues of $\nabla \Phi\left(x^{*}\right)$ are strictly negative. Considering the Taylor's expansion of $\Phi(x)$ around $x^{*}$, and having in view that $\nabla f\left(x^{*}\right)=0$, we get:

$$
\begin{aligned}
\frac{d x}{d t} & \cong \Phi\left(x^{*}\right)+\nabla \Phi\left(x^{*}\right)\left(x-x^{*}\right) \\
& =-\left[\nabla f\left(x^{*}\right)+\nabla^{2} f\left(x^{*}\right)\left(x-x^{*}\right)\right] \\
& =-\nabla^{2} f\left(x^{*}\right)\left(x-x^{*}\right)
\end{aligned}
$$

But, $\nabla^{2} f\left(x^{*}\right)$ is positive definite by the assumption of the theorem. Therefore its eigenvalues $\lambda_{i}>0$, for all $i=1, \ldots, n$. By the Poincaré-Lyapunov theory it follows that $\lim _{t \rightarrow \infty} y(t)=0$, or $x(t) \rightarrow x^{*}$ as $t \rightarrow \infty$.

The following theorem shows that $f(x(t))$ is strictly decreasing along the solution of (3).

Theorem 2.2. Let $x(t)$ be the solution of (3). For a fixed $t_{0} \geq 0$ if $\nabla f(x(t)) \neq 0$ for all $t>t_{0}$, then $f(x(t))$ is strictly decreasing with respect to $t$, for all $t>t_{0}$.

Proof. We have:

$$
\begin{aligned}
\frac{d f(x(t))}{d t} & =\nabla f(x(t))^{T} \frac{d x(t)}{d t} \\
& =-\nabla f(x(t))^{T} \nabla f(x(t)) \\
& =-\|\nabla f(x(t))\|_{2}^{2}
\end{aligned}
$$

Since $\nabla f(x(t)) \neq 0$ when $t>t_{0}$, it follows that $d f(x(t)) / d t<0$, i.e. $f(x(t))$ is strictly decreasing with respect to $t>t_{0}$.

Observe that the ordinary differential equation (3), associated to (1), is a gradient system (Ref. 14, pp.199). Gradient systems have special properties that make their flows very simple. For gradient system (3) at regular points $x$, characterized by the fact that $\nabla f(x) \neq 0$, the trajectories cross level surfaces of the function $f(x)$ orthogonally. Nonregular points are equilibria of the system, and if $x^{*}$ is an isolated minimum of $f(x)$, then
$x^{*}$ is an asymptotically stable equilibrium of the gradient system (3).

## 3. The gradient flow algorithm for unconstrained optimization

As we have seen, solving the unconstrained optimization problem (1) has been reduced to that of integration of the ordinary differential equation (3) with initial condition (4). Now we shall consider a discretization of this ODE as well as the corresponding integration scheme.

Let $0=t_{0}<t_{1}<\cdots<t_{k}<\cdots$ be a sequence of time points for the time $t \geq t_{0}$. Consider $h_{k}=t_{k+1}-t_{k}$ the sequence of time distances between two successive time points. With these, let us consider the following time-steeping discretization of (3):

$$
\begin{equation*}
\frac{x_{k+1}-x_{k}}{h_{k}}=-\left[(1-\theta) \nabla f\left(x_{k}\right)+\theta \nabla f\left(x_{k+1}\right)\right] \tag{5}
\end{equation*}
$$

where $\theta \in[0,1]$ is a parameter. From this we get:

$$
x_{k+1}=x_{k}-h_{k}\left[(1-\theta) \nabla f\left(x_{k}\right)+\theta \nabla f\left(x_{k+1}\right)\right] .
$$

When $\theta=0$ the above discretization is the explicit forward Euler's scheme. On the other hand, when $\theta=1$ we have the implicit backward Euler's scheme. But,

$$
\nabla f\left(x_{k+1}\right)=\nabla f\left(x_{k}\right)+\nabla^{2} f\left(x_{k}\right) \delta x_{k}+\Phi\left(\delta x_{k}\right)
$$

where $\delta x_{k}=x_{k+1}-x_{k}$ and $\Phi\left(\delta x_{k}\right)$ is the remainder satisfying $\left\|\Phi\left(\delta x_{k}\right)\right\|=O\left(\left\|\delta x_{k}\right\|^{2}\right)$. Therefore

$$
x_{k+1}=x_{k}-h_{k}\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right]^{-1}\left[\nabla f\left(x_{k}\right)+\theta \Phi\left(\delta x_{k}\right)\right] .
$$

Omitting the higher order term $\Phi\left(\delta x_{k}\right)$ we get:

$$
\begin{equation*}
x_{k+1}=x_{k}-h_{k}\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right]^{-1} \nabla f\left(x_{k}\right), \tag{6}
\end{equation*}
$$

for any $\theta \in[0,1]$. Considering $x_{0}$ as the initial guess, then (6) defines a series $\left\{x_{k}\right\}$. The convergence of (6) is given by

Theorem 3.1. Let $\left\{x_{k}\right\}$ be the sequence defined by (6) and $x^{*}$ a solution of (1), such that $\nabla^{2} f\left(x^{*}\right)$ is positive definite. If the initial point $x_{0}$ is close enough to $x^{*}$, then:
(i) If $\theta \in[0,1]$ and $h_{k}>0$ is sufficiently small, then $x_{k}$ converges linearly to $x^{*}$.
(ii) If $\theta=1$ and $h_{k} \rightarrow \infty$, then $x_{k}$ converges quadratically to $x^{*}$.

Proof. (i) From (6) we have:

$$
\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right]\left(x_{k+1}-x_{k}\right)=-h_{k} \nabla f\left(x_{k}\right)
$$

hence:

$$
\begin{equation*}
x_{k+1}=x_{k}-h_{k}\left[\nabla f\left(x_{k}\right)+\theta \nabla^{2} f\left(x_{k}\right)\left(x_{k+1}-x_{k}\right)\right] . \tag{7}
\end{equation*}
$$

Substracting $x^{*}$ from both sides of (7) and having in view that $e_{k}=x_{k}-x^{*}, x_{k+1}-x_{k}=$ $e_{k+1}-e_{k}$ and $\nabla f\left(x^{*}\right)=0$, we get:

$$
e_{k+1}=e_{k}-h_{k}\left[\nabla f\left(x_{k}\right)-\nabla f\left(x^{*}\right)+\theta \nabla^{2} f\left(x_{k}\right)\left(e_{k+1}-e_{k}\right)\right] .
$$

Now using the mean value theorem we have:

$$
e_{k+1}=e_{k}-h_{k}\left[\nabla^{2} f\left(\xi_{k}\right) e_{k}+\theta \nabla^{2} f\left(x_{k}\right)\left(e_{k+1}-e_{k}\right)\right],
$$

where $\xi_{k} \in\left[x_{k}, x^{*}\right]$. Solving for $e_{k+1}$, we have:

$$
\begin{equation*}
e_{k+1}=\left\{I-h_{k}\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right]^{-1} \nabla^{2} f\left(\xi_{k}\right)\right\} e_{k} \tag{8}
\end{equation*}
$$

Considering the norm of both sides of this equality we obtain:

$$
\begin{equation*}
\left\|e_{k+1}\right\| \leq \varphi\left(x_{k}, \xi_{k}, \theta, h_{k}\right)\left\|e_{k}\right\| \tag{9}
\end{equation*}
$$

where

$$
\begin{equation*}
\varphi\left(x_{k}, \xi_{k}, \theta, h_{k}\right)=\left\|I-h_{k}\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right]^{-1} \nabla^{2} f\left(\xi_{k}\right)\right\| . \tag{10}
\end{equation*}
$$

From (9) we see that if $\varphi\left(x_{k}, \xi_{k}, \theta, h_{k}\right)<1$, then $e_{k}$ converges to zero linearly. With these, selecting $\xi_{k}=x_{k}$, we can write:

$$
\begin{equation*}
\varphi\left(x_{k}, \xi_{k}, \theta, h_{k}\right) \leq\left(1-\frac{h_{k} \lambda_{\min }^{k}}{1+h_{k} \theta \lambda_{\max }^{k}}\right)<1 \tag{11}
\end{equation*}
$$

where $\lambda_{\min }^{k}$ and $\lambda_{\max }^{k}$ represents the minimum and the maximum eigenvalues of $\nabla^{2} f\left(x_{k}\right)$, respectively. Therefore, from (9) it follows that $\lim _{k \rightarrow \infty} e_{k}=0$ linearly, i.e. $x_{k} \rightarrow x^{*}$ linearly.
(ii) Consider $\theta=1$ in (7), we get:

$$
\frac{x_{k+1}-x_{k}}{h_{k}}=-\left[\nabla f\left(x_{k}\right)+\nabla^{2} f\left(x_{k}\right) \delta x_{k}\right],
$$

where $\delta x_{k}=x_{k+1}-x_{k}$. When $h_{k} \rightarrow \infty$ the above relation reduced to

$$
\nabla f\left(x_{k}\right)+\nabla^{2} f\left(x_{k}\right) \delta x_{k}=0
$$

which is the Newton method applied to $\nabla f(x)=0$. When $x_{k}$ is sufficiently close to $x^{*}$, as we know the Newton method is quadratically convergent, proving the theorem.

Remark 3.1. From (9) and (11), with $\theta=1$, we have:

$$
\left\|e_{k+1}\right\| \leq p_{k+1}\left\|e_{0}\right\|
$$

where

$$
p_{k+1}=\prod_{i=0}^{k}\left(1-\frac{h_{i} \lambda_{\min }^{i}}{1+h_{i} \lambda_{\max }^{i}}\right) .
$$

But, $\nabla^{2} f\left(x_{i}\right)$ is positive definite, therefore for all $i=1, \ldots k$,

$$
0<1-\frac{h_{i} \lambda_{\min }^{i}}{1+h_{i} \lambda_{\max }^{i}}<1
$$

So, $p_{k}$, for all $k$, is a decreasing sequence, from $(0,1)$, i.e. it is convergent. If $h_{i} \rightarrow \infty$, then for all $i=1, \ldots k$,

$$
1-\frac{h_{i} \lambda_{\min }^{i}}{1+h_{i} \lambda_{\max }^{i}} \rightarrow 1-1 / \kappa\left(\nabla^{2} f\left(x_{i}\right)\right)
$$

Clearly, if there is an $i$ for which $\kappa\left(\nabla^{2} f\left(x_{i}\right)\right)$ is close to 1 , then the convergence of the algorithm is very rapid.

Based on (6), for solving (1), the following algorithm can be presented:

## Algorithm GFUO (Gradient Flow Unconstrained Optimization )

Step 1. Consider the initial point $x_{0} \in R^{n}$, a parameter $\theta \in[0,1]$, a sequence of time step size $\left\{h_{k}\right\}$ and an $\varepsilon>0$ sufficiently smal. Set $k=0$.

Step 2. Solve for $\delta x_{k}$ the system

$$
\begin{equation*}
\left[I+h_{k} \theta \nabla^{2} f\left(x_{k}\right)\right] \delta x_{k}=-h_{k} \nabla f\left(x_{k}\right) \tag{12}
\end{equation*}
$$

Step 3. Update the variables: $x_{k+1}=x_{k}+\delta x_{k}$.
Step 4. Test for continuation of iterations. If $\left\|\nabla f\left(x_{k}\right)\right\| \leq \varepsilon$, stop; otherwise set $k=$ $k+1$ and continue with step 2 .

As the theorem 3.1 recommends, the GFUO algorithm is quadratically convergent if $\theta=1$ and $h_{k} \rightarrow \infty$. The problem is how to choose the sequence $h_{k}$. The most direct idea is to choose $h_{k}$ in such a way that the matrix of the system (12) to be positive definite. The following theorem suggests how to choose the value $h_{k}$ of time distances between two successive time points.

Theorem 3.2. If $h_{k}>\max \left\{-\frac{1}{\lambda_{i}^{k}}, i=1, \ldots, n\right\}$, where $\lambda_{i}^{k}, i=1, \ldots, n$, are the eigenvalues of $\nabla^{2} f\left(x_{k}\right)$, then $\left[I+h_{k} \nabla^{2} f\left(x_{k}\right)\right]$ is positive definite.

Proof. The matrix $\nabla^{2} f\left(x_{k}\right)$ is symmetric, i.e. it has real eigenvalues $\lambda_{i}^{k}, i=1, \ldots, n$. There exists a matrix $P$ such that

$$
P^{-1} \nabla^{2} f\left(x_{k}\right) P=\operatorname{diag}\left(\lambda_{1}^{k}, \ldots, \lambda_{n}^{k}\right)
$$

Therefore $P^{-1}\left[I+h_{k} \nabla^{2} f\left(x_{k}\right)\right] P=I+h_{k} \operatorname{diag}\left(\lambda_{1}^{k}, \ldots, \lambda_{n}^{k}\right)$, which is positive definite when $1+h_{k} \lambda_{i}^{k}>0$, for all $i=1, \ldots, n$.

In order to see the complexity of the GFUO algorithm let us denote

$$
a_{i}=\frac{h_{i} \lambda_{\min }^{i}}{1+h_{i} \lambda_{\max }^{i}}
$$

and consider $a_{j}=\min \left\{a_{i}: 0 \leq i \leq k\right\}$. Then

$$
p_{k+1}=\prod_{i=0}^{k}\left(1-a_{i}\right) \leq\left(1-a_{j}\right)^{k+1}
$$

i.e. $\left\|e_{k+1}\right\| \leq p_{k+1}\left\|e_{0}\right\| \leq\left(1-a_{j}\right)^{k+1}\left\|e_{0}\right\|$. Thus, the number of iterations required to obtain an accuracy $\left\|e_{k+1}\right\|=\left\|x_{k+1}-x^{*}\right\| \leq \varepsilon$, starting at point $x_{0}$, is bounded by

$$
\frac{\log _{2} \varepsilon-\log _{2}\left\|e_{0}\right\|}{\log _{2}\left(1-a_{j}\right)}-1
$$

This expression depends on the final accuracy, on the initial estimation of the optimal point, as well as on the distribution of eigenvalues of the Hessian matrices of function $f$ along the iterations.

## 4. Numerical experiments

In order to see the performances of the algorithm GFUO we present some numerical experiments obtained with a Fortran implementation of it. In all experiments we have considered $\theta=1$. The tolerance $\varepsilon$ is chosen to be $10^{-7}$. The time step size $h_{k}$ is considered the same for all $k$, equal with $h$. The GFUO algorithm is compared with the Newton algorithm with backtracking:

$$
x_{k+1}=x_{k}-\lambda_{k} \nabla^{2} f\left(x_{k}\right)^{-1} \nabla f\left(x_{k}\right),
$$

where the steplength $\lambda_{k}$ is chosen to satisfy the first Wolfe condition:

$$
f\left(x_{k}+\lambda_{k} d_{k}\right) \leq f\left(x_{k}\right)+\alpha \lambda_{k} \nabla f\left(x_{k}\right)^{T} d_{k},
$$

by backtracking, starting with $\lambda_{k}=1$ and reducing this value as $\lambda_{k}=\lambda_{k} s$, where $\alpha=$ $0.0001, s=0.8$ and $d_{k}=-\nabla^{2} f\left(x_{k}\right)^{-1} \nabla f\left(x_{k}\right)$.

Example 1. (Full matrix)

$$
f(x)=\sum_{i=1}^{n} i x_{i}^{2}+\frac{1}{100}\left(\sum_{i=1}^{n} x_{i}\right)^{2} .
$$

Considering $n=1000$, table 1 gives the number of iterations subject to different initial points and values for time step size $h$.

Table 1. Number of iterations for different initial points and $h$ (GFUO and Newton).

| $\mathbf{n}=\mathbf{1 0 0 0}$ | $\mathbf{h}=\mathbf{1}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $x_{0}=[0.5, \ldots, 0.5]$ | 15 | 6 | 4 | 3 | 2 |
| $x_{0}=[10.5, \ldots, 10.5]$ | 18 | 7 | 4 | 3 | 2 |
| $x_{0}=[100.5, \ldots, 100.5]$ | 20 | 7 | 5 | 3 | 2 |
| $x_{0}=[1000.5, \ldots, 1000.5]$ | 22 | 8 | 5 | 4 | 2 |

Example 2. (Diagonal)

$$
f(x)=\sum_{i=1}^{n} \frac{i}{10}\left(\exp \left(x_{i}\right)-x_{i}\right)
$$

Table 2. Number of iterations for different initial points and $h$ (GFUO and Newton).

| $\mathbf{n}=\mathbf{1 0 0 0}$ | $\mathbf{h}=\mathbf{1}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | Newton |

Example 6. (Bidiagonal)

$$
f(x)=\sum_{i=1}^{n-1}\left(x_{i+1}-x_{i}^{2}\right)^{2}+\left(1-x_{i}\right)^{2}
$$

Considering the initial point $x_{0}=[-1.2,1, \cdots,-1.2,1]$, the following results are obtained:

Table 6. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{\mathbf{2}}$ | $\mathbf{h}=\mathbf{1 0}^{\mathbf{3}}$ | Newton |

| 2000 | 1211 | 137 | 31 | 22 | 18 |

Example 8. (Extended Rosenbrock function)

$$
f(x)=\sum_{i=1}^{n / 2} c\left(x_{2 i}-x_{2 i-1}^{2}\right)^{2}+\left(1-x_{2 i-1}\right)^{2}
$$

For the initial point $x_{0}=[-1.2,1, \ldots,-1.2,1]$, and $c=100$ the following results are obtained:

Table 8a. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 15 | 9 | 7 | 7 | 20 |
| 100 | 16 | 9 | 7 | 7 | 20 |
| 1000 | 17 | 10 | 8 | 7 | 20 |
| 2000 | 17 | 10 | 8 | 7 | 20 |

For $c=1000$ we get the following results:
Table 8b. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{\mathbf{3}}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 16 | 9 | 7 | 7 | 38 |
| 100 | 17 | 9 | 7 | 7 | 39 |
| 1000 | 18 | 10 | 7 | 7 | 39 |
| 2000 | 18 | 10 | 7 | 7 | 39 |

For $c=10000$ we get the results:
Table 8c. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |

| 1000 | 22 | 12 | 8 | 7 | 52 |
| 2000 | 23 | 12 | 8 | 7 | 52 |

For $c=10000$ we get the results:

Table 9c. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 21 | 12 | 8 | 7 | 108 |
| 100 | 22 | 12 | 8 | 7 | 108 |
| 1000 | 23 | 13 | 9 | 7 | 108 |
| 2000 | 24 | 13 | 9 | 7 | 108 |

Example 10. (Arrowhead function)

$$
f(x)=\sum_{i=1}^{n-1}\left(x_{i}^{2}+x_{n}^{2}\right)^{2}-4 x_{i}+3 .
$$

For the initial point $x_{0}=[1,1, \ldots, 1,1]$ the following results are obtained:

Table 10. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 7 | 6 | 6 | 6 | 7 |
| 100 | 7 | 6 | 6 | 6 | 7 |
| 1000 | 7 | 6 | 6 | 6 | 7 |
| 2000 | 7 | 6 | 6 | 6 | 7 |

Example 11. (Arrowhead-Bidiagonal function)

$$
f(x)=\left(x_{1}-x_{2}\right)^{2}+\sum_{i=2}^{n-1}\left(x_{i-1}+x_{i}+x_{n}\right)^{4}+\left(x_{n-1}-x_{n}\right)^{2} .
$$

For the initial point $x_{0}=[1,-1, \ldots, 1,-1]$ the following results are obtained:
Table 11. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | $\mathbf{h}=\mathbf{1 0}^{\mathbf{5}}$ | $\mathbf{h}=\mathbf{1 0}^{\mathbf{6}}$ | $\mathbf{h}=\mathbf{1 0}^{7}$ | Newton |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 17 | 17 | 17 | 17 | 18 |
| 100 | 19 | 19 | 19 | 19 | 20 |
| 1000 | 27 | 20 | 21 | 21 | 22 |
| 2000 | 29 | 21 | 21 | 21 | 22 |

Example 12. (Engval function)

$$
f(x)=\sum_{i=2}^{n-1}\left\{\left(x_{i-1}^{2}+x_{i}^{2}\right)^{2}-4 x_{i-1}+3\right\}
$$

For the initial point $x_{0}=[2, \ldots, 2]$ the following results are obtained:
Table 12. Number of iterations for different values of $h$ (GFUO and Newton).

| $\mathbf{n}$ | $\mathbf{h}=\mathbf{1 0}$ | $\mathbf{h}=\mathbf{1 0}^{2}$ | $\mathbf{h}=\mathbf{1 0}^{3}$ | $\mathbf{h}=\mathbf{1 0}^{4}$ | Newton |

| 10 | 10 | 8 | 8 | 8 | 9 |
| 100 | 10 | 8 | 8 | 8 | 9 |
| 1000 | 10 | 8 | 8 | 8 | 9 |
| 5000 | 10 | 8 | 8 | 8 | 9 |

## 5. Conclusion

In this paper we proposed a gradient flow approach of an unconstrained optimization problem, which basically is a particularization of the gradient flow approach of the nonlinear equality constrained optimization problem by Wang, Yang and Teo (Ref. 12). The corresponding algorithm is based on a two level implicit time discretization scheme with a splitting parameter $\theta$ of an ordinary differential equation associated to the original unconstrained optimization problem. It is shown that the algorithm converges to a local minimum of the optimization problem either linearly or quadratically, depending on the value of the splitting parameter. Numerical experiments show that the algorithm is comparable with that of Newton's, for some ill-conditioned problems being superior. At every step it is necesarry
to solve an $n$-dimensional algebraic system of linear equations, but unlike the Newton's method no linear search is required.
